POWER SEMICONDUCTOR USER'S MANUAL AND DATA BOOK

Editor: Woodson J. Savage III

WESTINGHOUSE ELECTRIC CORPORATION
SEMICONDUCTOR DIVISION
YOUNGWOOD, PENNSYLVANIA 15697

ACKNOWLEDGEMENTS

This book is the result of the efforts of a number of dedicated individuals. Contributing authors include:

J.D. Balenovich
R.L. Bonkowski
R.F. Chick
P.J. DelPalazzo
J.F. Donlon
T.B. Geary
W.H. Karstaedt
R.J. Lambie
K.G. Longenecker
M. Morozowich
W.S. Przybocki
D.E. Rieth
G.M. Sherbondy
J.E. Steiner
K.S. Tarneja

It is hoped that the Ⓦ Power Semiconductor User's Manual and Data Book will enable anyone using power semiconductors to do so more effectively. Any suggestions on how future editions of this book can be improved to better serve your needs will be greatly appreciated.

1 INTRODUCTION

1. PURPOSE

The purpose of this book is to enable persons in any job function (i.e. Purchasing, Design, Production, Engineering, Plant operation and maintenance, Quality Control, Marketing, etc.) to deal with power semiconductors more effectively, regardless of his or her technical background or experience level. Every effort has been made to present this material in a straightforward, easy-to-use format so that the reader can readily apply many of these practical suggestions and ideas directly to his or her job. The reader should note that, although Westinghouse forms and procedures are highlighted in the User's Manual, the information being presented is generally applicable to *any* manufacturer of power semiconductors.

The term "user" in this book refers to both the Original Equipment Manufacturer (OEM) who manufactures equipment utilizing power semiconductors and the End User who purchases, uses, and maintains this equipment.

Engineering terms and other "jargon" perculiar to power semiconductors are used only when needed in the User's Manual and are usually defined within the text or in the appendix. Note: No effort is made in this book to "educate" the reader on how a power semiconductor "operates" in a circuit or how a power semiconductor "works". There are many fine texts on these subjects for those persons interested in these engineering and physics phenomena.

The User's Manual and Data Book is actually two books in one! A brief description of how these two books are organized:

The **User's Manual** is arranged in a somewhat natural sequence of events—Selecting the Proper Power Semiconductor, Semiconductor Procurement, Incoming Inspection, Testing, Device Installation, Equipment Operation, Preventative Maintenance, Troubleshooting, Replacements, Safety, Reliability and Quality Control plus a special section on the manufacture of Ⓦ Power Semiconductors. Sections can be read independently or in any desired sequence depending upon the reader's interest and need.

The **Data Book** offers detailed specifications on the complete line of Westinghouse Power Semiconductors. The General section includes a master cross reference type number index by JEDEC 1N, 2N, and 3N part numbers and industry alpha and numeric part numbers. Using this index, the reader can rapidly locate any power semiconductor part number for which Westinghouse offers an exact or suggested replacement along with the page number of the data sheet for the recommended Westinghouse device. In addition, this section contains the Ⓦ Selling Policy, Warranty Information, Delivery Lead Time Guide Lines, Military/Hi-Rel Product Capabilities, General Application Data Sheets, a Quick Service Directory listing key contacts for special assistance, and a complete listing of Ⓦ Semiconductor Sales Offices and Authorized Ⓦ Semiconductor Distributors. The remaining four product sections—Assemblies, Rectifiers Thyristors (SCR's and RBDT), and Transistors each are subdivided into their respective major product subgroups. Easy-to-use Product Capability Graphs and Product Selector Guides are provided at the beginning of each product section to enable the reader to quickly locate technical data for any given product.

2. POWER SEMICONDUCTOR OVERVIEW

Westinghouse is a world leader in the manufacture of high power semiconductors. In 1952, Westinghouse introduced the first silicon rectifier; in 1957, the first high voltage rectifier stack assemblies were introduced; in 1958, silicon transistors were added, followed by a line of SCR's in 1959. From this infancy, the semiconductor market has mushroomed into virtually every industrial, military, and consumer market. These markets include steel mill drives, space vehicles, and calculators, to name just a few. Even though Westinghouse was a pioneer in many areas of semiconductor development and currently holds basic patents used today by almost every semiconductor manufacturer, the strategic decision was made to concentrate efforts in the power segment (1 ampere and above) of the semiconductor spectrum (see figure 1.1) with primary emphasis on the 40 ampere and above market.

The semiconductor industry's business spectrum is not as homogeneous as one might expect. Each of these power segments represent different technologies, industries, applications, and markets. One popular

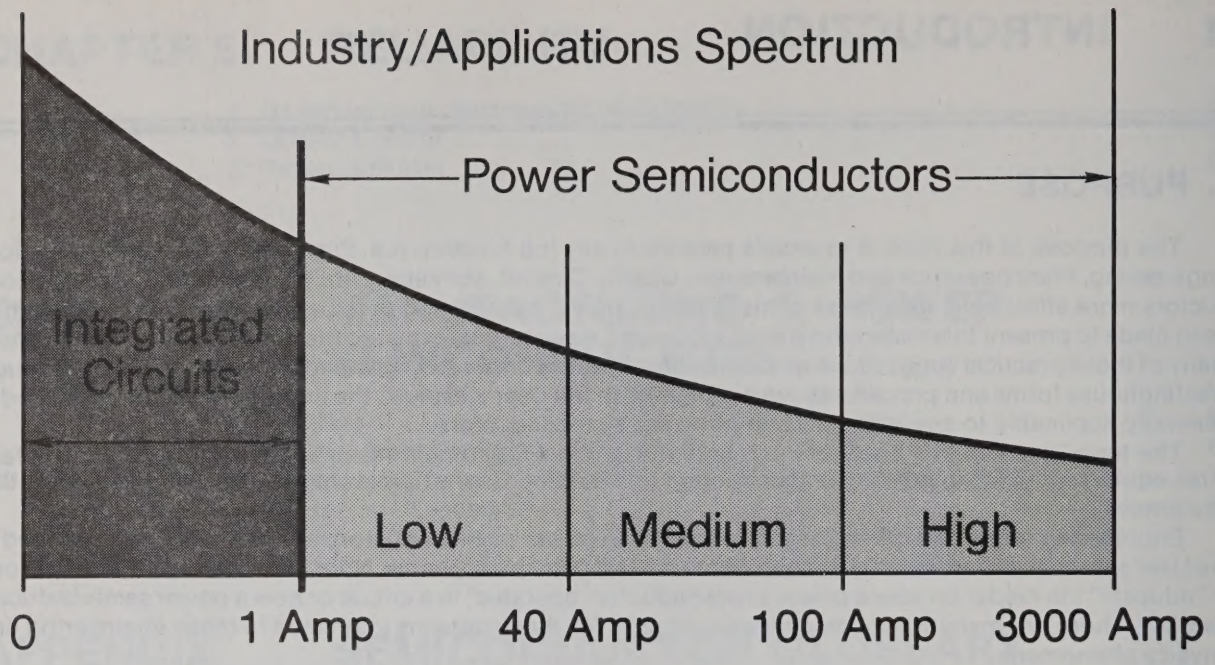

Figure 1.1 Semiconductor Business Spectrum

misconception about the semiconductor industry involves pricing. Integrated circuits, for example, have generally exhibited tremendous price declines—often tenfold or more. People usually assume that since integrated circuits exhibit this type of falling price phenomenon so should all other semiconductors. A little analysis will show why this theory does not hold. Integrated circuit prices, as well as all discrete product prices, fluctuate with *volume*—not with time as many people mistakenly observe. Integrated circuits serve *very* high volume markets and are made and tested with highly automated equipment. The power semiconductor market (especially the higher power areas), by comparison, is a much smaller, lower volume market serving primarily industry and military needs. These products are more custom made and tested to a customer's specification than to common generic type number. Historically, power semiconductor prices did show modest declines as new products were brought on the market initially at premium prices so the semiconductor manufacturers could attempt to recoup the substantial R&D expenses necessary to develop these products. Now, however, many new products—especially higher current and/or voltage extensions of existing products are priced more consistent with prevailing market prices. Today, many power semiconductor types are in the mature stage of their product life cycles. As a result, there are less cost reduction possibilities to offset the ever increasing inflation caused by higher material, labor, and factory expense costs. Therefore, price trends on many power semiconductors now and in the future will be upward instead of downward.

3. Ⓦ POWER SEMICONDUCTOR PRODUCT LINE

Westinghouse offers a comprehensive line of power semiconductors including rectifiers, thyristors—SCR's (silicon controlled rectifiers) and RBDT (reverse blocking diode thyristor), transistors, and assemblies.

• General Purpose Rectifiers	1-2200 Amperes Up to 4KV
• Fast Recovery Rectifiers	6-1400 Amperes Up to 3.2 KV .2-5μs
• Phase Control SCR's	10-1400 Amperes Up to 3 KV

• Fast Switching SCR's	40-900 Amperes Up to 2.2KV 10-80μs
• Reverse Blocking Diode Thyristor (RBDT)	22-80 Amperes Up to 1 KV 2,000-4,000A/μs
• General Purpose Transistors	.5-15 Amperes 30-150V
• High S.O.A. Transistors	1.5-25 Amperes 30-250V
• High Power Switching Transistors	50 Amperes 400-500V

Many of these products are available in a variety of packages including axial lead mount, diamond mount, flat base, studless, stud mount, and disc mount. All of these products are available mounted on air, oil, or water cooled heat sinks in a variety of circuit configurations; these assemblies offer average current ratings from .5 amperes to 10,000 amperes or more with voltage capabilities as high as 688 KV for some high voltage stack designs.

The Ⓦ Data Book covers the vast majority of products and assemblies currently available; however, increased current ratings, voltage ratings, and/or improved turn-off and reverse recovery times will continue to evolve as a result of new product developments and improved production yields. Therefore, the reader is encouraged to contact a Westinghouse sales representative regarding any application(s) that might fall into any of these "fringe" areas.

4. IMPORTANCE OF POWER SEMICONDUCTORS

Power semiconductors have grown from laboratory curiosities to brute-force industrial components which have become competitive necessities in the marketplace. The potential advantages of solid-state power electronics over electromechanical equipment are well known: increased reliability and service life, reduced size and maintenance. In some cases, there is a sizeable cost advantage, while in other cases the performance capabilities can be achieved in no other way. Table 1.1 shows a complete matrix of industrial applications that can use Westinghouse Power Semiconductors (See page 13).

At least three current trends indicate that power semiconductors will become even more important to the user:

1. The growing shortage of oil and gas and the growing environmental concern will stimulate the utilization of clean electrical power in countless new areas now predominantly served by other forms of energy.
2. Efficiency in the manipulation and control of electrical power will have increasing priority as the rising cost of power forces the abandonment of techniques which are "short-term cheap but long-term wasteful."
3. The evolution of present applications and the creation of new applications will cause increasing demands for speed, precision, and reliability in power control that can be satisfied by no other technology.

For these reasons, power semiconductors are penetrating many new application areas and outmoding many traditional design approaches. Product engineering departments accustomed to well established design procedures involving Ward-Leonard drives, relay logic, or selenium rectifiers are faced with extinction overnight if they cannot adapt to the higher levels of complexity and analytical sophistication made possible and made necessary by solid-state electronics. While many technologies evolve over a period of decades—leaving adequate reaction time for business planning—this is not usually the case with power electronics. Solid state technology typically moves from an insignificant share of a market to a dominant share in a period of only 2 to 4 years. The universal S-curve showing the capture of a market by a product which takes advantage of power electronics is shown in Figure 1.2. Thus, a company which does not keep up-to-date in this new technology can easily lose a secure market position because of inadequate reaction time.

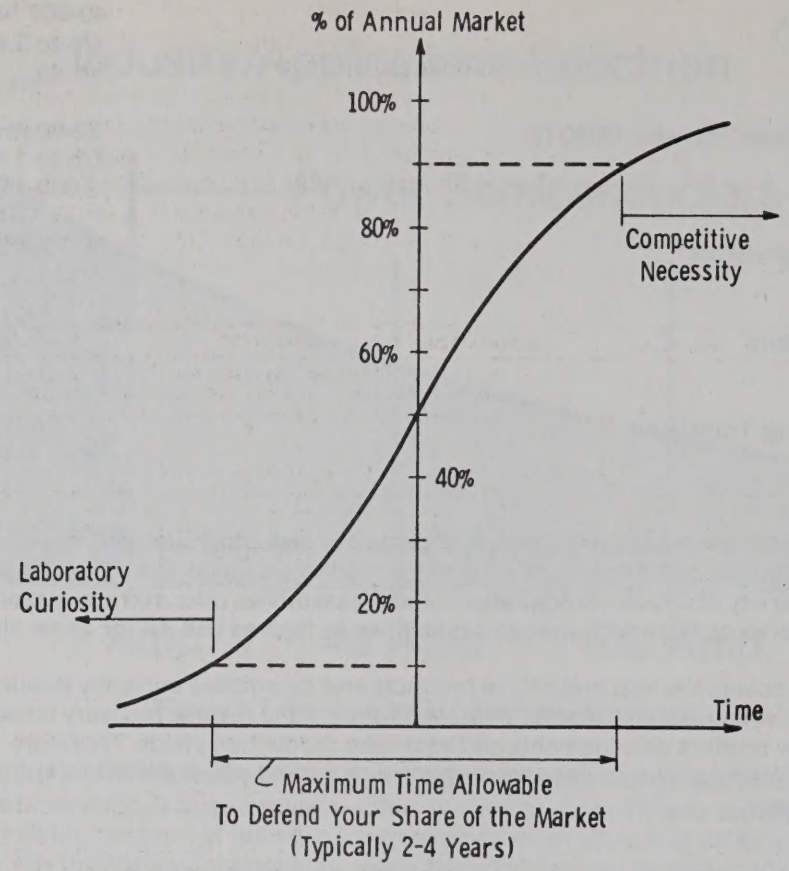

Figure 1.2 Universal s-curve showing market penetration by a product which takes advantage of power electronics.

5. MANUFACTURER /OEM/ END USER RELATIONSHIP

Historically, this relationship has tended to be split into two independent relationships: (1) The semiconductor manufacturer and the customer, the original equipment manufacturer (OEM). (2) The OEM and the customer, the end user. With the growth and acceptance of power semiconductors into virtually every market segment, as well as the emergence of trends brought on by energy, environmental, and safety considerations,

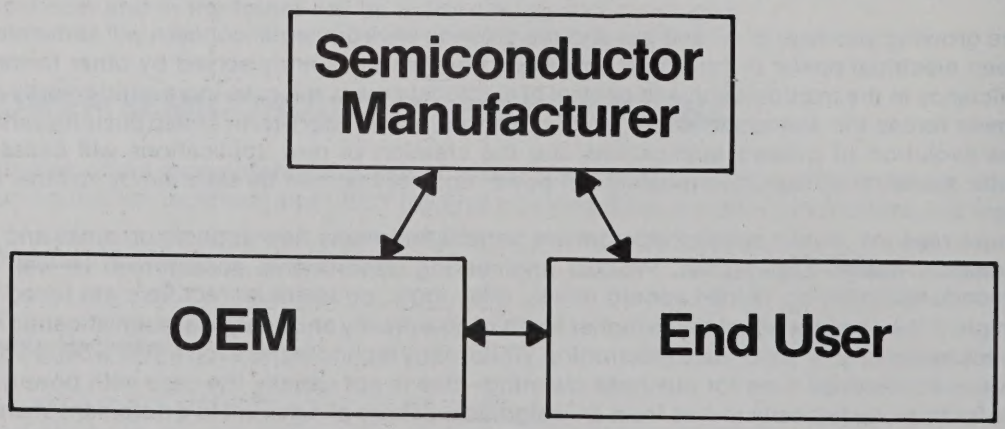

Figure 1.3 Semiconductor Manufacturer, OEM, End User Relationship.

the manufacturer, OEM, and end user relationship has become much more dynamic and comprehensive (shown by the diagram in Figure 1.3). The semiconductor manufacturer has come to recognize that both the OEM and the end user are "Users" of power semiconductors, whether directly or indirectly. The end user is really the ultimate customer—the one who purchases, uses, and maintains the equipment that was built and sold by the OEM who, in turn, purchased power semiconductors from the component manufacturer. The end user wants reliable, efficient, easy-to-maintain equipment that will meet the necessary environmental and safety standards while providing maximum performance at minimum cost. Not until the semiconductor manufacturer, the OEM, and the end user collectively work together can a semiconductor be produced and a piece of equipment be designed that will fulfill all of the end user's needs. This is a shared relationship that, if properly performed, will be mutually rewarding for all concerned.

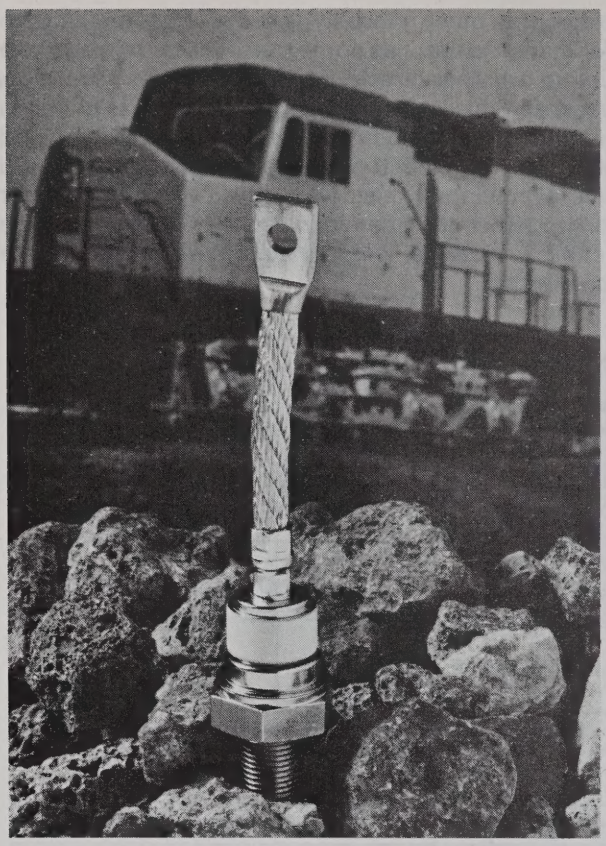
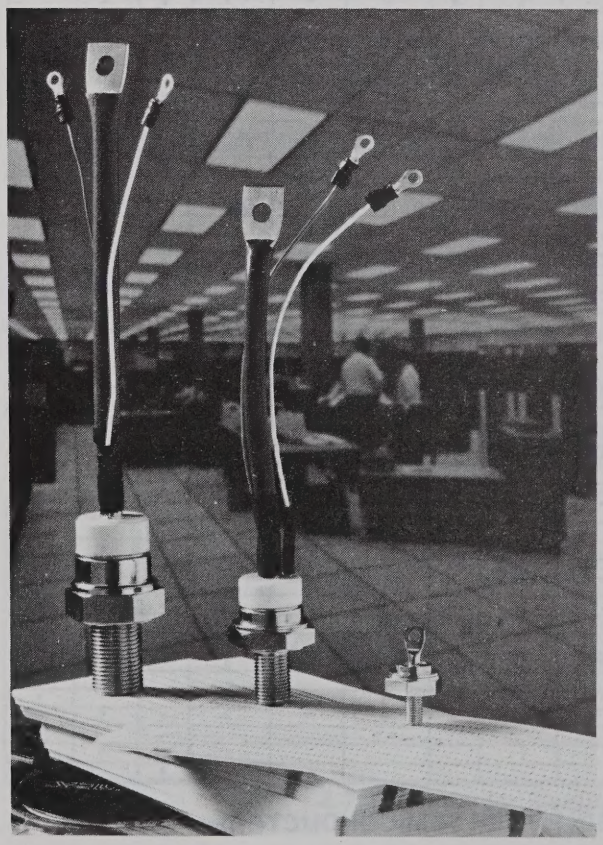
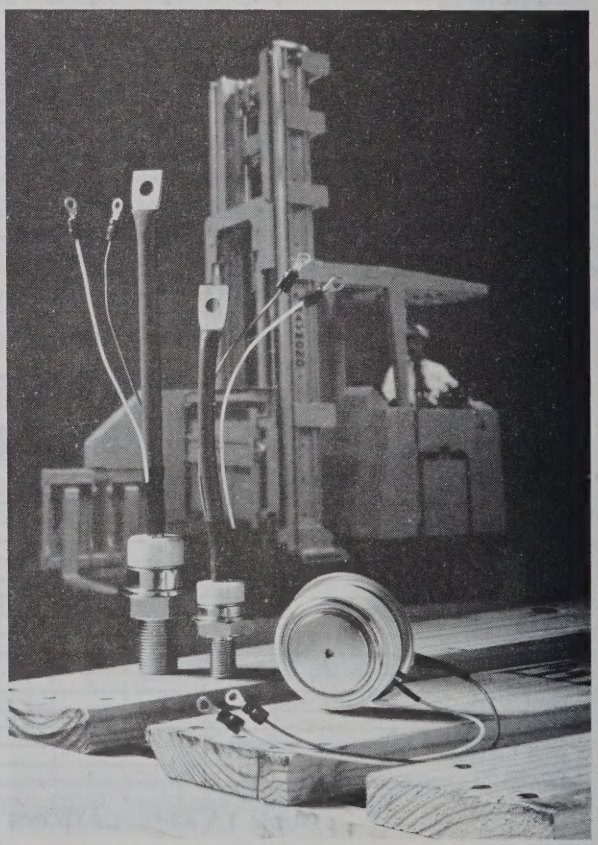
Table 1.1 APPLICATIONS FOR ⓦ POWER SEMICONDUCTORS







2 SELECTING THE PROPER POWER SEMICONDUCTOR FOR YOUR APPLICATION

1. BASIC SEMICONDUCTOR PARAMETERS DEFINED

The primary tool for selecting the proper semiconductor to meet a given requirement is the technical data sheet. In order to use the data sheets effectively, one must first understand the significance of some of the more important parameters used in rating these semiconductors. The following apply to all types of semiconductors:

$T_{J(MAX)}$—Maximum allowable junction temperature. This is a very critical parameter upon which all device ratings are based. Typically, most SCR's have an upper operating junction temperature limit of 125°C (with some high temperature series up to 150°C capability); most transistors have an upper operating junction temperature limit in the range of 150°C to 175°C; and most rectifiers have an upper operating junction temperature limit in the range of 175°C to 200°C. If these respective values are exceeded, the device becomes vulnerable to rapid failure. Of course, proper derating below these maximum limits is necessary in the actual application to assure reliable performance.

$T_{c(MAX)}$—Maximum allowable case temperature. Since the user of semiconductors has no way of actually measuring the junction temperature inside of a device package, the case temperature becomes a practical, useful value which can be measured and monitored. As a result, data sheets usually show the current carrying capability of a device as a function of its case temperature. The case temperature is directly related to the junction temperature by the device characteristic, $R_{\theta JC}$ (thermal impedance).

$R_{\theta JC}$—Thermal impedance, junction to case. $R_{\theta JC}$ is measured in degrees centigrade per watt and is determined by the device construction and materials used. This parameter indicates the ability of the device to transfer heat away from the junction and out through the device case—the lower the value, the better.

Other basic device parameters by family type that are essential for the semiconductor user to know in the selection effort are as follows:

Family Type	Input/ Control	Output	Losses	Overload	Other Special
RECTIFIERS	NONE	$I_{F(av)}$ (1) V_{RRM} (2)	V_{FM} (3), I_{RRM} (4)	I_{FSM} (5)	t_{rr} (6)
SCR's	I_{GT} (6)	$I_{T(av)}$, (1) V_{RRM} (2)	V_{TM} (3), I_{RRM} (4)	I_{TSM} (5)	di/dt, (7) dv/dt, (8) t_{on}, (9) t_q (10)
TRANSISTORS	I_B (6)	I_C, (1) V_{CE} (2)	$V_{CE(SAT)}$, (3) $V_{BE(SAT)}$, (4) I_{CEO} (5)	NONE	SOA, (7) t_{on}, (8) t_{off}, (9) h_{FE} (10)

Table 2.1 BASIC SEMICONDUCTOR DEVICE PARAMETERS

The following expansion of the items in the table explain their importance:

RECTIFIERS

(1) $I_{F(av)}$—Maximum full cycle average forward current (measured with an average reading meter) at a

specified case temperature. This is the maximum amount of current that can be controlled or rectified by any given device.

(2) V_{RRM} —Maximum repetitive peak reverse voltage. This is the maximum allowable voltage that a device will block in the reverse direction. An associated parameter, V_{RSM}, defines the device capability to withstand non-repetitive reverse voltage peaks of less than five millisecond duration. This parameter typically ranges from zero to 25% above the repetitive values.

(3) V_{FM} —Maximum forward voltage drop at a specified forward current and device case temperature. The large majority of the losses in a rectifier are due to the forward voltage drop. Therefore, low forward drops are very desirable in high power devices because less power is dissipated ($P=V_{FM} \times I_{F(av)}$).

(4) I_{RRM} —Maximum reverse leakage current at V_{RRM}. Low reverse leakage currents are desirable for the same reason as a low V_{FM}, less power (watts) to be dissipated ($P=V_{RRM} \times I_{RRM}$).

(5) I_{FSM} —Maximum one-half cycle ($60H_Z$) peak surge current (under load). Ability to withstand current surges in excess of the rated operating current extends the application capability of a rectifier. This characteristic is non-repetitive in nature and, by definition, may occur only 100 times within the life of the device. An associated parameter, I^2t, is used to coordinate sub-cycle fuse clearing time with sub-cycle fault rating of a rectifier.

(6) t_{rr} —Maximum reverse recovery time relates to the time required for the reverse current spike to dissipate after a rectifier stops conducting forward current. This characteristic is especially important on a class of rectifiers called "fast recovery" devices. Because all rectifiers are essentially "self-operated" switches, they have finite switching times. This characteristic becomes important when one wishes to rectify (or switch) at high frequencies.

SCR's

(1) $I_{T(av)}$ —Maximum allowable average forward current at a specified conduction angle and case temperature. If a conduction angle of 180° is specified, this parameter would be the same as $I_{F(av)}$ in a rectifier. However, unlike a rectifier, the conduction angle of an SCR can be controlled from 0 to 180° (typically, a data sheet lists five or six of these angles). The conduction angle defines that part of the sine wave during which the device is conducting current.

(2) V_{RRM} —Maximum repetitive reverse blocking voltage. The same comments apply here as for V_{RRM} of a rectifier. The SCR in addition to having reverse blocking capability will also block voltage in the forward direction. V_{DRM} is the designation for the maximum value of repetitive forward blocking voltage. Most SCR designs are symmetrical in nature—that is, the forward and reverse repetitive blocking voltage capabilities for a given device are equal ($V_{DRM}=V_{RRM}$). Both repetitive voltage ratings (V_{RRM} V_{DRM}) have corresponding non-repetitive voltage ratings, V_{RSM} and V_{DSM}

(3) V_{TM} —Maximum forward voltage drop at a specified forward current and device case temperature. The same comments apply here as for V_{FM} in a rectifier.

(4) I_{RRM} —Maximum reverse leakage current at V_{RRM}. Again, as with a rectifier, low leakage currents, I_{RRM}, are desirable as less power will be dissipated in the blocking (off-state) mode. In addition, as an SCR has repetitive forward voltage capability, V_{DRM}, it also has a forward leakage current, I_{DRM}

(5) I_{TSM} —Maximum peak surge current for a given number of cycles at $60H_Z$. As with a rectifier, this characteristic is by definition non-repetitive and may occur only 100 times within the life of the device. In addition, following this current surge, the repetitive forward blocking voltage, V_{DRM}, is not guaranteed. This subject is treated in more detail in the Ⓜ Thyristor Surge Suppression Ratings Application Data Sheet in the General section of the Data Book. An associated parameter, I^2t, is used for fuse coordination.

(6) I_{GT} —Minimum DC gate current to trigger (turn-on) an SCR at stated conditions of temperature and forward blocking voltage. This characteristic specifies the absolute minimum amount of current that must be provided from a logic source to switch an SCR from blocking voltage (off-state) to conducting current (on-state). For more information, see the SCR Gate Turn-on Characteristics Application Data Sheet in the General section of the Data Book.

(7) di/dt—Maximum rate of rise of peak current allowable with respect to time during SCR turn-on. Because an SCR requires a finite time to turn on, only a very small area of the junction is conducting current at the instant the device is triggered on. If the current is building up very quickly, it must all go through this very small area. When the specified di/dt limit is exceeded, the device can develop a hot spot which can destroy the unit. This is generally not a problem in $60H_Z$ phase control applications but becomes a problem in DC switching applications (e.g. inverters) or in capacitor discharge circuits. When comparing di/dt ratings of different manufacturers be sure the ratings are both repetitive or nonrepetitive and that the ratings are based on the same set of test conditions.

(8) dv/dt—Minimum rate of rise of peak voltage with respect to time which will cause switching from the off-state to the on-state. When the dv/dt limit is exceeded, the potential danger exists of turning the SCR back on when it should remain off. As with di/dt this is generally only a problem in square wave or step function applications. Review all test conditions when comparing dv/dt ratings of different manufacturers—dv/dt can be expressed as either a linear or an exponential function.

(9) t_{on} —Time required for the forward current to reach 90 percent of its final (or maximum) value when switching from the off-state to the on-state under specified conditions. Switching times are important for two reasons—they affect the upper frequency at which the device may be operated and to some degree they determine the system efficiency. When considering frequency of operation (or in pulse applications, the desired pulse width), it becomes simply a matter of whether or not the device can be turned on and off fast enough to satisfy the requirements. Power losses when switching from blocking voltage to conducting current can be a significant consideration for determining system efficiency.

(10) t_q —Turn-off time relates to the time required for an SCR to switch from conducting current to blocking forward voltage. Turn-off time is important for essentially the same reasons as turn-on time. Turn-off time is not critical in most 60 cycle phase control applications; however, a special class of SCR's called "fast switching" devices are used in inverters, choppers, and other high frequency circuits. In these types of applications, the designer must be careful to select a device offering the optimum combination of current handling capability, voltage blocking capability, and turn-off time capability. Due to the wide variety of fast switching applications, data sheet turn-off conditions do not necessarily reflect actual circuit operating conditions. Contact Ⓦ if help is needed in selecting the proper device.

TRANSISTORS

(1) I_C —Collector current. In most applications, this is the current that is manipulated to perform some desired function. In a series regulator, for example, the collector current can be increased or decreased by base current control, depending upon what the load requires.

(2) V_{CE} —Collector-to-emitter voltage. This is similar to V_{RRM} in rectifiers and SCR's in that it represents the device blocking capability in the off-state. There are many related designations: V_{CEO}, V_{CES}, V_{CER}, etc. They differ only in the third subscription letter which indicates the condition of the base: O-open, R-resistor, S-shorted, etc.

(3) $V_{CE(SAT)}$ —Collector-emitter saturation voltage. When driving the base of a transistor, a point is reached where increased base current no longer results in decreased collector-emitter voltage. This is saturation. $V_{CE(SAT)}$ is a measure of the voltage across that junction under saturation and is comparable to forward voltage drop in rectifiers and SCR's. $V_{CE(SAT)}$ and I_C lead to power losses in the transistor during saturated operation and therefore, are important considerations.

(4) $V_{BE(SAT)}$ —Base-emitter saturation voltage. The same general comments apply here as for $V_{CE(SAT)}$ except the comments now refer to a base-emitter rather than a collector-emitter condition. High $V_{BE(SAT)}$ or large variations in $V_{BE(SAT)}$ will cause corresponding changes in $V_{CE(SAT)}$

(5) I_{CEO} —Collector-to-emitter leakage current with the base open. This is usually the primary leakage loss in a transistor. This characteristic is comparable to I_{RRM} in rectifiers or SCR's. While low values of leakage are desirable to minimize power losses, low leakage is not necessarily synonymous with reliability.

(6) I_B —Base current. The function of the base current in a transistor is similar to that of the gate current in an SCR. However, in a transistor, current must be provided into the base as long as the transistor is to be kept on, whereas, the SCR only requires an initial pulse of current to turn it on.

(7) SOA—Safe Operating Area. SOA is a voltage-current plot which describes an area in which the transistor can operate safely. A time limit is given for the collector voltage and collector current that can occur simultaneously in the transistor. Forward bias SOA ratings require the base-emitter to be forward-biased throughout the time that the peak power condition exists and is usually measured in a resistive circuit. A related term is forward current stability, denoted by the symbol I_{SB}. Safe operation of a transistor during inductive switching when a transistor in series with an inductor is turning off necessitates consideration of additional characteristics. The inductance will keep current flowing for some period of time. During this time, the voltage is increasing across the transistor creating a VxI product or power dissipation. Because the base-emitter is reverse-biased, the transistor cannot dissipate as much power. The energy that a transistor can support is denoted by the abbreviation E_{SB}. Inductive switching ratings can be used as a guide to compare transistor capabilities, but actual capabilities must be verified in the actual circuit.

(8) & (9) t_{on} & t_{off} —Turn-on time and turn-off time. These are important parameters in transistors for essentially the same reasons given in the SCR remarks.

(10) h_{FE} —DC current gain under specified conditions of collector current and collector-emitter voltage. This transistor characteristic is the ratio of DC collector current to DC base current. This amplification factor determines the amount of output (I_C) that is generated by a given input (I_B). For example, if h_{FE} is 20 at I_B =1 ampere, then I_C is 20 amperes.

2. CONFUSING TERMINOLOGY—MANUFACTURER VERSUS USER INTERPRETATION

Many users and designers have either been lucky or have learned the hard way how to properly interpret a semiconductor manufacturer's data sheet. Unfortunately, many conventional semiconductor terms and definitions can have double meanings, depending upon whether they are being interpreted from the manufacturer's or the user/designer's point of view. What a semiconductor manufacturer might define as a maximum (minimum) value on a data sheet could well be a minimum (maximum) value for the designer and user. A few examples utilizing SCR terminology will illustrate this dilemma:

Data Sheet Terminology	User or Designer's Interpretation Might Be	Semiconductor Mfgr's Actual Meaning	Remarks
(1) Maximum I_{GT}=150 ma	Does this mean that no more than 150 ma is needed to turn-on these SCR's?	All SCR's supplied will have gate currents less than or equal to 150 ma. User must supply *more than* 150 ma to assure proper SCR turn-on. In fact, 3 to 5 times as Max. I_{GT} is desirable for SCR turn-on in certain applications.	Here, a value defined as maximum by the manufacturer is for the user or designer, an absolute minimum design limit.
(2) Maximum blocking or off-state voltage V_{DRM}, V_{RRM} =1200 volts.	Does this mean that some devices received will block or support less than 1200 volts?	All devices supplied will support *at least* 1200 volts; however, this limit *cannot* be exceeded in the application.	In this case, the manufacturer's maximum is also, the designer's or user's maximum limit.
(3) Minimum di/dt – 200 A/μs	Does this mean that 200 A/μs can be exceeded in a given application?	All devices supplied will withstand a rate of current rise (di/dt) of *at least* 200 A/μs; however, this limit *cannot* be exceeded in the application.	Here, the manufacturer's minimum value becomes the user's or designer's maximum design limit.
(4) Typical turn off time t_q=40μs	Can this typical turn-off time be relied on in a given application?	This 40μs turn-off time *only* represents an average value for the product family and is *not* a guaranteed limit.	Typical values should *not* be relied upon by the designer or user as guaranteed values.

Table 2.2 Confusing Data Sheet Terminology

Realistically, data sheets should be written from the user and designer's view point rather than the manufacturer's device-oriented point of view—however, since most users and designers have been "weaned" on this existing terminology, a change in philosophy would create only more confusion. To help those who have yet to conquer data sheet terminology, the following suggestions are offered:

The safest way to interpret a *maximum* or *minimum* data sheet limit is to recognize that (1) they *both* represent *worst case* designer or user conditions, (2) they *both* are *guaranteed* by the semiconductor manufacturer. As for "typical" values, don't rely on them as maximum or minimum design limits in an application. If a "worst case" limit rather than a "typical" value is needed for a particular application, have the semiconductor manufacturer guarantee the design limit needed either by actual testing or written certification. If still in doubt about how to interpret a given data sheet parameter, call the semiconductor manufacturer for clarification.

3. HOW TO USE THE WESTINGHOUSE DATA BOOK

There are four easy ways to locate technical data in the Westinghouse Data Book:

Device Type Number Search

(1) IF ONLY THE PRODUCT TYPE NUMBER IS KNOWN:

Go to the Master Cross Reference Type Number Index in the GENERAL section of the Data Book. Using this JEDEC and alpha/numeric industry index, the reader can rapidly locate any power semiconductor product type number for which Westinghouse offers an exact or suggested replacement along with the page number of the recommended Westinghouse product data.

(2) IF BOTH THE PRODUCT FAMILY AND THE PRODUCT TYPE NUMBER ARE KNOWN:

Go the the alpha/numeric Product Type Number index at the beginning of the approprate generic PRODUCT section (Assemblies, Rectifier, Thyristor-SCR's and RBDT, or Transistors). Using this index, the reader can turn directly to the page location of a given product type number.

General Application Search

(3) IF A SPECIFIC PRODUCT APPLICATION REQUIREMENT IS KNOWN:

Go to the appropriate PRODUCT section (Assemblies, Rectifier, Thyristor-SCR's and RBDT, or Transistors), look under the appropriate product subgroup (i.e. General Purpose or Fast Recovery for Rectifiers), and scan the Product Capability Graphs and Product Selector Guides. These graphs and guides are presented in order of increasing average current so the reader can quickly locate a suitable Westinghouse product type and corresponding page number data location.

(4) IF BOTH A SPECIFIC PRODUCT APPLICATION REQUIREMENT AND THE DESIRED PRODUCT PACKAGE IS KNOWN:

Go to the Ⓦ Data Book Table of Contents for the location of the appropriate PRODUCT section, product subgroup, and package type. The page number shown marks the beginning of the desired data section; the data for a given package type is listed in order of increasing average current rating to simplify the reader's search.

4. KNOW YOUR APPLICATION REQUIREMENTS

Many applications using general purpose rectifiers or transistors and phase control SCR's require the user only to consider such basic parameters as current, voltage, and temperature when developing a new design, working on a conversion or an equipment upgrade, or looking for a replacement device. However, there can be many secondary parameters which can adversely affect desired equipment operation—especially if devices are used in series and/or parallel combinations. Most fast recovery rectifiers, high power switching transistors, and fast switching SCR's require close scrutiny by the user on essentially *all* device parameters to assure proper equipment operation.

To assist the user in selecting the proper power semiconductor for a given application, Westinghouse has developed a series of Application Checklist/Work Sheets in the following areas: (1) General Purpose and Fast Recovery Rectifiers (2) Phase Control SCR's (3) Fast Switching SCR's (4) Power Transistors (5) Assemblies. To use a particular form, simply make a xerox copy and fill it out. With your application requirements down on paper in a logical order, it will be easier to locate a suitable device by self-selection or by calling or writing the semiconductor manufacturer for a device recommendation.

P.S. Even if you have already selected a device yourself, it might be worthwhile getting a confirmation from the manufacturer.

To assist the user in searching for replacement devices, a handy Device Identification Checklist has been developed. A copy of this form is presented on page 54.

GENERAL PURPOSE AND FAST RECOVERY RECTIFIER APPLICATION CHECKLIST

(Make copy for each use)

1. APPLICATION: _____

_____

2. CIRCUIT:

Sketch circuit (showing all component values including inductances) or attach drawing

3. CIRCUIT VOLTAGE:

- Maximum reverse voltage across rectifier _____ V
- Maximum expected transient voltage _____ V
- Desired voltage safety factor _____
- Preferred rectifier device voltage rating _____ V
- Other _____ _____

4. CIRCUIT CURRENT: (sketch waveform(s) on back of page)

- Average forward current* _____ A
  - Waveform and frequency _____
  - Duty cycle _____ %
- Overload peak current (waveform) _____ A
  - Duty cycle _____ %
  - Pulse width _____
  - Resume operation following overload ☐ YES ☐ NO
- Peak surge current (waveform) _____ A
  - Pulse width _____
  - Number of cycles _____
- Other _____ _____

*If paralleling is required, state method of current sharing ____

5. THERMAL:

- Cooling Medium (check one) -

☐ AIR - ☐ Natural Convection, altitude ____ feet or

☐ Forced _____ LFM _____ CFM**

**Duct cross-sectional area ____

☐ WATER - _____ GPM flow rate

☐ OIL (immersed) - Type ____ Manufacturer _____

☐ OTHER _____

- Cooling medium maximum temperature, °C _____
- If heat sink is known, specify $R_{\theta SA}$ _____ °C/W.
- Other thermal considerations

6. MECHANICAL:

- Desired package type (check one) -

☐ LEAD MOUNT

☐ STUD MOUNT - { ☐ STANDARD POLARITY OR ☐ REVERSE POLARITY }

☐ DISC MOUNT

☐ OTHER

☐ NO PREFERENCE

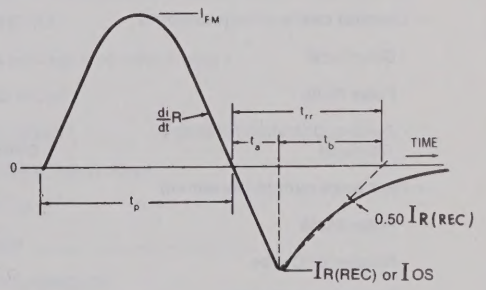
- Special size, weight, or other restrictions _____

_____

FOR APPLICATIONS REQUIRING FAST RECOVERY CHARACTERISTICS, COMPLETE THE FOLLOWING SECTION -

7. RECOVERY CHARACTERISTICS: (If required, sketch waveform(s) on back of page)

- Maximum reverse recovery time allowable, t_{rr} _____
- Recovery time, t_a _____
- Recovery time, t_b _____
- Maximum overshoot current, $I_{R(REC)}$ _____ A
- Peak current, I_{FM} _____ A
- Pulse width, t_p _____
- Rate of current fall, di_R/dt _____ A/μs
- Waveform _____
- Maximum junction temperature _____ °C



8. PROJECT REQUIREMENTS: Quotation Due Date _ _____

- Quantity Required _____
- Timetable _____

Long-range Potential _____

- Other Remarks _____

_____

_____

☐ Special screening and/or high reliability test requirements are attached.
☐ Also quote on this application using Ⓦ assemblies.

PHASE CONTROL SCR APPLICATION CHECKLIST

(Make copy for each use)

1. APPLICATION: _____

_____

2. CIRCUIT:
Sketch circuit (showing all component values including inductances) or attach drawing

3. CIRCUIT VOLTAGE:

- Maximum peak forward and/or reverse voltage across SCR _____ V
- Maximum expected transient voltage _____ V
- Desired voltage safety factor _____
- Preferred SCR voltage rating _____ V
- Other _____ _____

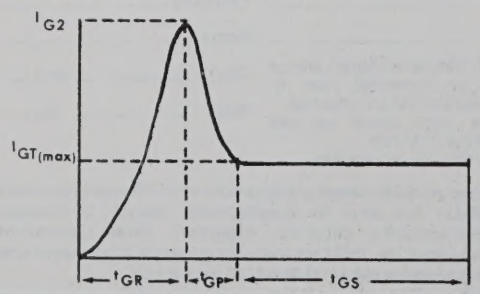
4. CIRCUIT CURRENT: (sketch waveform(s) on back of page)

- Maximum continuous SCR current* - □DC, □AVERAGE, or □RMS _____ A
- Phase - □1φ, □3φ, □6φ, or □OTHER _____
- Conduction angle - □Sine or □Square, degrees _____
- Current waveform, frequency, and duty cycle _____
- Overload peak current (waveform) _____
  - Duty Cycle _____ %
  - Pulse Width _____
  - Resume Operation Following Overload □YES □NO
- Peak surge current (waveform) _____ A
  - Pulse Width _____
  - Number of Cycles _____
  - Assymetry (L/R ratio) _____
- Other _____ _____

*If paralleling is required, state method of current sharing: _____

5. GATE DRIVE AVAILABLE:

- I_{G2} _____ A
- t_{GP} _____ μs
- t_{GR} _____ μs
- t_{GS} _____ μs
- $I_{GT\ (max)}$ 25°C _____ ma
- Forward gate source voltage _____ V



6. THERMAL:

- Cooling Medium (check one) -
  - □ AIR - □ Natural Convection, altitude _____ feet or
  - □ Forced _____ LFM _____ CFM **
  - ** Duct cross-sectional area _____
  - □ Water - _____ GPM flow rate
  - □ OIL (immersed) - Type _____ Manufacturer _____
  - □ OTHER - _____
- Cooling medium maximum temperature, °C _____
- If heat sink is known, specify $R_{\theta SA}$ _____ °C/W.
- Other thermal considerations _____

Wise Semiconductor Procurement Means Good Resource Management and That Involves Everyone!

3 SEMICONDUCTOR PROCUREMENT

1. SPEND SEMICONDUCTOR DOLLARS WISELY.

Each user must consider several facets of device and supplier capability in order to make intelligent procurement decisions concerning power semiconductors. Suggestions for evaluation of the "total" value of a power semiconductor supplier are provided in Section 2. Section 1 deals briefly with other suggestions for consideration prior to selecting a device and placing an order: (1) "total" cost, including costs over and above the price of the device and (2) engineering-related financial considerations, such as efficiency, reliability, and device availability versus electrical capability.

Total Cost. The price of a power semiconductor is certainly one of the major items for consideration prior to selection of a device to satisfy the user's needs. However, a user must also consider other costs in order to optimize "total" cost. Packaging, transportation, insurance charges, and hardware requirements associated with a device are easily measurable, although often disregarded. Other total cost considerations are not measured as easily, but can prove to be very significant alternatives. For example, blanket contracts, blanket orders, letters of intent, and other types of purchase agreements are generally vehicles used to obtain lower device prices, however, these agreements help to reduce other cost factors. When a power semiconductor manufacturer has advance knowledge of on-going user requirements, better planning is possible. The net result is improved reproducibility, reduced delivery lead time which helps to minimize user safety stock, and better on-time shipping performance.

Often when a user buys several different semiconductor type numbers in the same product family, a savings can be obtained by ordering only the best rated unit (current, voltage, etc.) for all needs, thus qualifying for a larger volume price discount. Combining purchases for device types of different voltage ratings is usually the most practical way to achieve a higher volume price discount (this is especially true for the lower voltage ratings of a given product type); sometimes combining various current ratings of the same package type will also result in savings. If in doubt, ask the manufacturer to review your semiconductor procurement list and recommend the most economical purchase option. The manufacturer will be glad to help since it is easier to fill one large order for a single device type than many small orders for different part numbers. In addition, the user saves time and money in incoming inspection, inventory costs, improved delivery performance, and standardization of parts.

Another frequently overlooked cost factor relates to special handling. Costly set-up charges can be avoided and better price stability and shorter delivery lead times can be realized if the user limits the number of releases and maximizes release quantities for each device. A decision to enter an order through an authorized distributor to avoid the generally higher minimum release of a manufacturer can often be a reduction in total cost even though the individual device price may be higher; however, beware of counterfeit rebranded devices. Deal only with *authorized* distributors. Trying to save a few dollars on a unit price basis can add significantly to total costs if the devices are determined to be defective at a later date. Extra inspection steps, such as a requirement for government source inspection, also can cause delayed shipments and increased costs because of delays incurred while waiting for arrival of inspectors.

Engineering Related Financial Considerations. Efficiency of equipment, cost of maintenance, reliability, and the cost of auxiliary and protective circuitry are significant items for review in order to obtain a true picture of the cost of a particular power semiconductor. It is often difficult to determine a dollar value for each of these factors, but each item must be considered, nonetheless, if an intelligent procurement decision is to be made.

In a field of rapid technological improvement such as power semiconductors, new devices are introduced at frequent intervals. A single new device often replaces two or more existing device types and/or procurement of new completely tested assemblies of devices on heat sinks (where semiconductor purchase dollars may rise, but total equipment costs decline) is often more economical for the user than handling individual parts. Review of the latest available devices is, therefore, an essential ingredient in wise power semiconductor procurement.

The user must also determine the optimum trade-off between electrical parameters as these parameters relate to the ability of the device manufacturer to reproduce devices consistently. For example, selection of a fast switching SCR often requires trade-offs among blocking voltage, current rating, and turn-off time to assure availability in large quantities.

Adequate safety factors on device ratings are another significant cost-related design consideration. Manufacturers of power semiconductors normally warrant products to meet specific electrical parameters. The designer must apply safety factors to assure the integrity of the application, but application of excessive safety factors can be costly.

Power semiconductor manufacturers spend considerable time and money to develop device families with useful, user-acceptable, ratings. When possible, users should attempt to incorporate these "standard" devices into applications to assure themselves of the best price and product availability. Special electrical test requirements and/or mechanical modifications normally add to cost and delivery lead times.

2. EVALUATING A POWER SEMICONDUCTOR SUPPLIER

The traditional method for evaluating the value of a supplier-price, delivery, service (P,D,S)—is a gross oversimplification of the measurement criteria. The P,D,S rule could cause one to "short change" oneself and prevent the company from realizing the total value of capabilities and services offered by truly good suppliers. Eighteen key items to be used for comparing suppliers have been identified and discussed below under four major categories—General Support, Pre-Order Period, Order Period, and Post-Order Period (see Table 3.1).

Each of the categories (or each of the individual items) must be weighted according to the needs or requirements of each user organization. That user must then evaluate each available supplier for the most important categories (or items). The manufacturer(s) scoring the highest total rating represents the best "total value" supplier to the user.

This method for evalution is presented as a tool to aid in the selection of a supplier. The method is not simply a means of reducing the values of a supplier to a numerical score; the purpose is to identify and quantify the key areas where potential power semiconductor supplier(s) can represent real value to a user.

GENERAL SUPPORT
- —Sales coverage
- —Distributor support
- —Technological leadership
- —Product reproducibility

PRE-ORDER PERIOD
- —Technical information support
- —Application engineering assistance
- —Sample/prototype service
- —Quotation response
- —Competitive price and delivery

ORDER PERIOD
- —Order acknowledgement
- —Customer information service
- —On-time shipments
- —Advance warning of shipping delays
- —Condition of shipments

POST-ORDER PERIOD
- —Reliability
- —Settlement of claims
- —Warranty
- —Replacement of obsolete device types

Table 3.1 Supplier Evaluation Checklist

GENERAL SUPPORT

Sales coverage is the primary link between a power semiconductor manufacturer and the user. A good factory salesperson or manufacturer's representative is a problem solver, not merely an "order taker". A good salesperson is knowledgeable about the total product offering and service capability of the manufacturer and can therefore resolve pre-order, order, or post-order problems or obtain anwers to questions that might arise during these periods.

Distributor support is an important factor in complete service support. Authorized distributors supply local, reliable service for production as well as emergency requirements by providing ample inventories and many value-added features. In addition, these distributors offer a broad spectrum of complimentary products.

Technological leadership assures the user that product which is purchased is manufactured with modern techniques and exhibits state-of-the-art electrical parameters and mechanical configurations. Power semiconductor manufacturers invest millions of dollars annually to keep products and processes up-to-date. New generations of devices or redesigned, upgraded versions of existing products can drastically affect the competitive market position of the user. New power semiconductors can lower or at least maintain equipment costs, offer improved energy utilization, support a cleaner, quieter environment, provide greater system reliability, reduce equipment size and weight, provide increased safety to equipment operators and employees, and can offer new and expanded operating capabilities. Since successful users must incorporate new technologies in equipment in order to remain competitive, they must be extremely conscious of the technological leadership qualities of their power semiconductors suppliers.

Product reproducibility is an often overlooked, but extremely important term for evaluation of power semiconductor manufacturers. Many design engineers have experienced the unfortunate situation of designing a system which incorporates a new state-of-the-art device sample produced under laboratory conditions and then be unable to obtain the device in sufficient volume and/or at a reasonable price. The yield-dependent nature of power semiconductor production dictates the necessity for a manufacturer to maintain a well-controlled production process in order to provide adequate quantities at acceptable price levels. A total value power semiconductor supplier must combine those controls with a full understanding of user requirements—device specifications, required quantities, production timetables.

PRE-ORDER PERIOD

Technical information support includes such items as product data sheets, application data sheets, seminars, technical papers, application handbooks, product newsletters, price lists, cross reference guides, and other semiconductor information. These written communications are the user's most reliable and most comprehensive source of information regarding a given manufacturer's products, services, and capabilities. The completeness and accuracy of the material presented, its pertinence to the user's application, and the rate of response in supplying the requested information are all important factors in providing meaningful, technical information.

Application engineering assistance can be a valuable resource if properly used. While application engineers cannot be expected to design a customer's circuit, they can help a customer avoid misapplication of devices or can assist in solving many different product-related application problems. Frequently, special ratings and other data can be generated for particular customer applications. Failed semiconductors can be examined to determine the cause of failure so that corrective action(s) can be taken. Good application assistance means easy access to engineers who possess a high level of expertise and a willingness to help solve a problem for the customer.

Sample/prototype service relates to the semiconductor manufacturer's willingness to provide samples for qualification for new designs as well as for second source approval. The delivery of the sample(s) must be prompt, with test data when appropriate. Prompt sales follow-up to assure satisfactory performance in the application is required for "total-value" service.

Quotation response refers to such items as speed, accuracy, and completeness of quotation information. Good performance at this phase of a negotiation is essential to prevent serious errors in the order processing and post-order periods.

Competitive price and delivery are treated as a single entity because both items usually must fall within some pre-determined maximum allowable user limit in order to be considered as a valid quotation. The price quoted must fairly reflect the product and services being provided by the semiconductor manufacturer. The delivery time quoted must be realistic; and when a fast delivery is required, the delivery time quoted must truly reflect a best effort from the manufacturer.

ORDER PERIOD

Order acknowledgement must be prompt and accurate to assure timely shipment. Delays at this point are

totally unnecessary and are completely avoidable if the items in the General Support and Pre-Order Periods have been treated properly by the power semiconductor manufacturer.

Customer information service reduces user cost when provided promptly in a complete and accurate manner. Little or no effort on the part of the user should be required to determine the status of most orders.

On-time shipments are a true measure of the stated capability of a power semiconductor manufacturer. Historical on-time shipment performance becomes a benchmark for determination of supplier "believability" in all facets of service. Willingness to recognize and discuss reasons for missed delivery promises is another item to consider when evaluating a power semiconductor supplier.

Advance warning of shipping delays is essential if a user is to have time to adjust equipment production schedules to accommodate the delay. Major causes of late semiconductor deliveries are usually the result of shifts in production yields, test correlation problems, production and/or equipment through-put limitations, and/or out-of-spec incoming material component parts. Knowledge of an impending delay must be transmitted to the user immediately.

Condition of shipments when received at the user's plant, to a great extent, depends upon how the product was packaged for shipment and the quality control procedures observed prior to and during shipment. Experienced packers using specially designed cartons and packing material for power semiconductors can make the difference as to whether or not a shipment of product will survive the trip from supplier to user. However, condition of shipments is also a function of the freight carrier employed to move the product and the types of carriers available from the supplier's facility to the user's facility is an important consideration.

POST-ORDER PERIOD

Reliability generally refers to long term product performance - actual field service experience. Reliability is a shared responsibility among the semiconductor manufacturer, the original equipment manufacturer, and the end user and is often regarded as the single most important item by all three groups.

Settlement of claims is often not considered as being very important; however, one only needs to have a single bad experience to really appreciate its value. Settlement of claims includes such things as shipment shortages, incorrect pricing and invoicing, rejected material, transportation charges, customer rework orders, and cancellation charges. There can be a wide discrepancy among various semiconductor manufacturers as to how promptly, efficiently, and fairly such claims are handled.

Warranty is like insurance — no one ever needs it until it is too late. If nothing else, a warranty is at least an indication of the confidence a manufacturer has in the products and services provided. A warranty should define the extent of coverage and the time span of the guarantee. The size of a semiconductor manufacturer and more importantly, the ability to financially handle a large claim must be considered — especially on certain jobs where a high percentage of the equipment cost is due to the power semiconductors.

Replacement of obsolete device types is a continuous problem for the user — both the original equipment manufacturer and the end user of the equipment. Although a fairly high degree of standardization exists within the power semiconductor industry, new designs are evolving constantly, often with slightly different mechanical dimensions and configurations and more often with improved electrical ratings. A "total value" manufacturer provides information and, whenever possible, product as replacement for old or obsolete designs. Since the end user of equipment is usually attempting to procure a few spare parts to get equipment back into operation, it is important for the OEM to maintain a small inventory of replacement semiconductors to support renewal parts business or to support orders for old equipment designs without expensive and lengthy engineering redesign. The ability of the power semiconductor manufacturer to support those needs is another significant criteria for selecting a supplier.

Several precautions must be taken when evaluating suppliers using this or any other method. The person (s) responsible for evaluating suppliers must recognize that within the organization different departmental functions (purchasing, engineering, production, maintenance, general management, research and development, etc.) will place a different degree of importance on each of the items under consideraton. Therefore, an attempt should be made to at least subjectively provide a composite weighting for each of the items that reflects the needs of the total organization. One should also recognize that the type of product or services being sought (commodity-type device versus special device type) as well as the amount of business to be placed (quantity required, lead time, second source requirements) can significantly alter the choice of suppliers. Thus, the best supplier choice under one set of conditions may not be the best choice under a different set of conditions. Finally, nothing is really ever stagnant. User needs change . . . Supplier's products, services, and capabilities also change over time. Therefore, a user must periodically (every 18 months to 2 years) re-evaluate or review the situation to determine whether or not the existing lineup of suppliers is still the best total value.

3. BUYER'S CHECKLIST

PRE-ORDER

Having selected the product required for a given application and having chosen the supplier, the following checklist will help to make the buyer's job easier and to minimize errors and delays:

- If a new customer, establish credit with the supplier prior to placing the purchase order.
- Identify the required device by describing with a single term, either drawing number plus revision, JEDEC number, or manufacturer part number.
- Establish total quantity required.
- Optimize total cost and delivery by considering available purchase agreements, minimum releases, authorized distributors, hardware, packaging and data requirements, standard catalog items versus specials.
- Specify requested shipping date *or* in-plant date.
- Provide complete and accurate "Ship To" and "Bill To" information.
- Specify shipping method (consider cost, transmit time, traceability, insurance cost.)
- Reference negotiation number or quotation number, if applicable.
- Specify tax exemption status.
- Send purchase order directly to manufacturer or authorized distributor.

ORDER

- Proofread acknowledgment.
- Contact supplier directly concerning order status.

POST-ORDER

- Contact the Returned Material Coordinator at the manufacturer concerning administrative errors, such as discrepancies on packing lists or invoices.
- Contact the Returned Material Coordinator at the manufacturer for authorization and specific return instructions prior to returning any material.

4. ENTERING AN ORDER

After selecting a device and a supplier, speed and accuracy are primary factors to consider when placing a purchase order. If a power semiconductor manufacturer can translate the information on the purchase order into factory working language quickly and accurately, the user has a much greater chance to receive the required parts in a timely manner. Chances for production line shutdowns and/or decreased production rates due to parts shortages are greatly reduced.

A concise, but complete, description of the following information on each purchase order will minimize supplier translation time and enhance translation accuracy. Remember that too much information can create as many translation errors as too little information.

1. "Ship To" address. Be sure to include company name, street, plant, department or building number, if applicable, city, state, and zip code.
2. "Charge To" or "Bill To" address. Provide the same information as in (1) above.
3. Purchase order number in a conspicuous location.
4. Note any special marks required on order acknowledgements, packing lists, or invoices.
5. Tax information concerning exemption from state and local taxes. Taxes must be charged if exemption information does not appear on the purchase order or if an exemption certificate, resale certificate, or direct pay permit is not on file with the supplier. Remember that state taxes are based on the "Ship To" address.
6. Description of parts required. In order of preference the best method for part description is (1) user part number or drawing number, specifying most recent revision, (2) JEDEC number, (3) manufacturer part number. Only one of the methods should be used for a single item on a purchase order. Use of more than one method of description (e.g. XYZ Corp. part number 378A94 Revision C or 1N1203) requires order entry personnel to cross check to assure that both descriptions identify exactly the same device. Avoid listing deviations to the device specified on the purchase order. If a JEDEC or supplier part number does not adequately

describe the required part, agree upon the deviations and assign a part number prior to entering the purchase order.

7. Quantity of parts required.

8. Unit price of parts required.

9. Special charges. List charges for environmental testing, special tooling, and/or service charges as separate items if pre-order quotation specified them in that manner.

10. Shipment method preferred. Remember that "best way" or "cheapest way" for the supplier may not be the best or cheapest method for the user.

11. Requested shipping date or in-plant date. Be certain to explain which date is being specified.

12. Negotiation or quotation number. If the supplier has assigned a number to the pre-order discussions, it is always good practice to repeat the number on the purchase order.

13. Special insurance charges, if applicable.

If accurate information is supplied in each of the categories above, entering the order and shipping product will be handled more smoothly. However, the user must consciously make an effort to reduce the time required to transmit an order to the supplier, while minimizing the possibility of interpretation and transmission errors. The best solution is obviously to eliminate extra steps in the order entry process. Time delays and the possibility of errors are automatically inserted when a purchase order is routed through a sales office or through some other intermediate mail stop. Transmission of order information via wire or telephone introduces additional possibilities for interpretation and transmission errors and legally, a manufacturer cannot begin work on an order without the confirming order document. Therefore, for most accurate and efficient order processing, a user should send the purchase order directly to the manufacturer or authorized distributor, when possible.

5. IN-PROCESS ORDER INFORMATION

Significant time intervals occur between the time a user generates a purchase order and the time the user receives the parts against that order. During that period of time it becomes the responsibility of the power semiconductor manufacturer or authorized distributor to keep the user advised of the status of the purchase order. Presentation of order status information by the manufacturer minimizes the time and expense that the user must incur to determine "what's happening."

Order Acknowledgement. The first step the supplier must take is to properly acknowledge receipt of a purchase order and advise the user of a shipping schedule. Although the manufacturer generally checks for accuracy, the user, upon receipt of the acknowledgement, should compare the information to the original order to determine if the order entry process was correct. Many production, shipping, receiving, and incoming inspection problems can be avoided by careful review of documents at this stage of the order.

Order Status. Information to the user does not stop at the order acknowledgement stage. In order to reduce expediting time and expense the manufacturer must continually reconfirm shipping schedules and provide advance warning for shipping delays that may occur.

The manufacturer must also establish a contact point at the factory so that schedule changes and/or questions that do arise can be handled quickly and effectively. The responsible salesperson is a good contact point, however, travel schedules often make that individual difficult to reach and a designated contact at the supplier is most often more convenient for the user.

Invoicing. The invoicing process differs slightly from supplier to supplier, however, a few key items must be presented:

- Invoices must be traceable to the original purchase order of the user. User purchase order number, device type, and unit price are normally considered critical criteria.
- Specific payment terms and address to which payment is to be remitted.
- Delineation of charges not specifically covered by the original purchase order such as transportation charges, insurance charges, special handling fees, etc.
- Date of invoice and date of shipment. These dates normally coincide, however, deviations do occur and must be presented clearly in order to prevent problems with terms of payment.

Test Data. User specifications sometimes specifically require the manufacturer to serialize devices and record test results on a sample basis or for 100% of the devices shipped. Additional requirements, such as a mercury exclusion clause or a certificate of compliance, are often specified. The manufacturer must present such information clearly and include the data with each shipment to reduce receiving and incoming inspection delays at the user's facility.

Ⓦ Order Acknowledgement. After a purchase order has been entered at the factory, a computer-generated order acknowledgement (yellow) for each item is sent to the customer.

(A sample acknowledgement is shown in Figure 3.1). Ⓦ terms and conditions of sale are printed on the reverse side of the form. Orders generally are acknowledged within twenty-four hours after receipt at the factory.

(1) Date that order was entered at the factory by Ⓦ.
(2) Customer purchase order number.
(3) "Charge To" address.
(4) "Ship To" address.
(5) Special remarks required on shipping or invoice documents.
(6) Shipment method if specified on purchase order.
(7) Item number.
(8) Quantity for specified item.
(9) Product type, part number.
(10) Unit price.
(11) Total value of specified item.
(12) Administrative notes.
(13) Requested ship date.
(14) Ⓦ scheduled ship date.
(15) Customer Services Representative responsible for this order.
(16) Ⓦ telephone number.

Any inquiries concerning an open purchase order should be directed to the designated Customer Services Representative at the factory.

Ⓦ Purchase Order Status Report. Ⓦ publishes an open purchase order status report to each customer on a weekly basis. The report has been designed to reduce expediting time and expense by providing timely order information and is mailed each Friday (with an identical copy to the responsible Ⓦ sales representative).

A sample of the order status report appears in Figure 3.2.

(1) Customer purchase order number.
(2) Quantity of parts on open order on the date of the report.
(3) JEDEC number, Ⓦ type, or customer drawing number and revision as specified on the purchase order.
(4) Date that the order was entered at the Ⓦ factory and the requested ship date.
(5) Original Ⓦ scheduled ship date and advance warning for revised schedule date, if required.
(6) Quantity of parts shipped by item since previous report, date of shipment, and shipment method.
(7) Pertinent product and/or planning information.
(8) Name of Customer Services Representative responsible for these orders. Any inquiries concerning an open purchase order should be directed to the designated Customer Services Representative.

In addition to the order status information, this report enables each customer to quickly identify any errors which may have occurred in the order entry process. Early detection of such errors can reduce post-shipment problems.

Each Ⓦ authorized distributor receives a copy of the order status report for purchase orders which they have placed with the factory so that the ultimate customer can receive quick order status information about Ⓦ power semiconductors whether the order is placed directly with Ⓦ or through an authorized Ⓦ distributor.

6. SHIPPING METHODS AND INSURANCE

Power semiconductors vary in size and weight from a small axial lead rectifier (.1 oz.) to large assemblies of devices on heatsinks (50 lbs.) This wide spectrum of sizes and weights enables the supplier to use several different types of shipping methods to transport the devices. However, these methods differ widely in cost, speed, size and weight limits, geographic coverage, traceability, and available insurance coverage. Since most power semiconductors are shipped on an f.o.b., point of shipment, freight collect basis, the supplier normally honors any specified routing from the user. If the user does not specify a preferred shipping method, the supplier will pick the most economical carrier who provides good service to the shipping facility. Remember, however, that "Best Way" or "Cheapest Way" to the supplier may not be best or cheapest to the user; all services are not available between all points. Therefore, it is a good practice to specify a particular shipment method on all purchase orders.

A brief description of the most common methods for shipping power semiconductors is given below. See Table 3.2 for a comparison of these methods relative to geographic coverage, size and weight limits, insurance, etc.

UPS

This carrier is probably the most popular for small parcel shipments. Transport is handled via truck and/or air (UPS Blue Label), depending upon distance. UPS limits shipments to 50 pounds per carton and 100 pounds per day to a single location.

PARCEL POST

Parcel Post is a branch of the U.S. Postal Service. The service is available to any domestic location with postal service. Packages are transported via truck and/or air. Weight is limited to 50 pounds per carton.

AIR PARCEL POST

Same as Parcel Post except with guaranteed air service. Rates are slightly higher than Parcel Post.

TRUCK

This method is the most economical for shipments over 100 pounds. Trucking firms are licensed to pick up and to deliver to specific states. Care must be taken when routing shipments to assure that the specified carrier can/will deliver to the desired destination. Transfers from one trucking firm to another are common.

AIR FREIGHT

Air shipments can be made via air freight forwarders or via conventional air lines cargo. Air freight forwarders, such as Emery, use any number of airline carriers and, therefore, can route packages quickly to almost any location. Some air forwarders, such as Federal Express, use their own fleet of aircraft to provide the same services. The forwarders are usually more expensive than conventional air lines cargo; however, specific airlines serve limited areas because of federal route restrictions and usually restrict service to scheduled flights of their own airline. Time is the big factor favoring air freight; most carriers offer next-day service to any served location for specific fee.

BUS

This method is seldom used, but is required when quick deliveries from other carriers is not available to remote areas.

Method	Weight Limits	Geographic Coverage from Youngwood, Pa.	Traceability	Insurance	Frequency of Service From Ⓜ Factory in Youngwood, Pa.
UPS	50 lbs./carton, 100 lbs. to a single location per day.	Continental U.S.	Must be traced from point of shipment. Takes from 1 to 3 weeks.	Automatic $50. Available up to $5,000 maximum.	1 pickup per day.
UPS Blue	50 lbs./carton, 100 lbs. to a single location per day.	California, Oregon, Washington, Georgia, Florida.	Must be traced from point of shipment. Takes from 1 to 3 weeks.	Automatic $50. Available up to $5,000 maximum.	1 pickup per day.
Parcel Post/Air Parcel Post	50 lbs./carton.	Worldwide.	Can only trace insured cartons. Takes from 4 to 8 weeks.	None automatic. Check Postal Service for rates.	2 pickups per day.
Truck	None.	Continental U.S.	Can be traced from either direction. Takes less than 1 week.	Depends on commodity rate. No extra available.	On demand.
Air Freight	None.	Worldwide.	Can be traced from either direction. Takes less than 1 week.	Full value coverage possible.	3 pickups per day.
Bus	50 lbs./carton.	Continental U.S.	Must be traced from point of shipment.	Automatic $50.00. Available up to $250.00 maximum.	Must deliver to terminal.

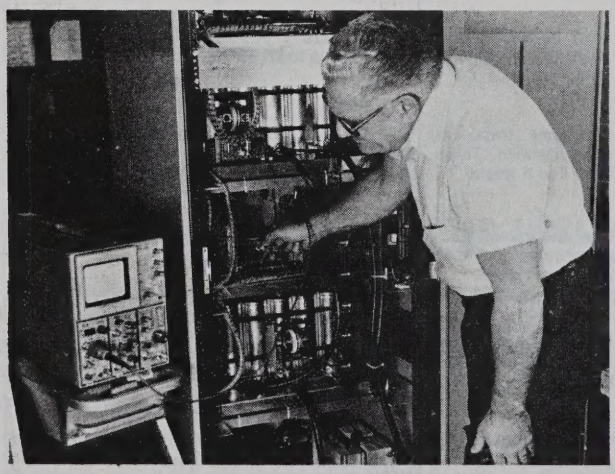
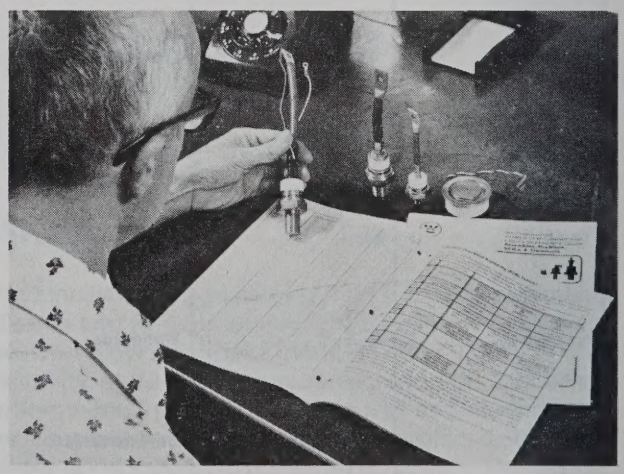
Cleaning



Trouble Shooting



Identification and Replacement

4 STANDARD OPERATING PROCEDURES FOR THE POWER SEMICONDUCTOR USER

1. RECEIVING

Most users have a fixed procedure for receiving shipments of power semiconductors. If a procedure does not exist, one should be established as quickly as possible to avoid receipt of damaged goods into inventory. An important item to remember is to examine each shipment carefully for evidence of rough handling and container damage. Most power semiconductor manufacturers ship on an f.o.b. point of shipment basis and, therefore, responsibility for the material is transferred at time of shipment. Users must note package damage when signing for a shipment and file a claim against the carrier. Accepting a damaged shipment without noting this fact when signing for the shipment practically eliminates the possibility of a successful claim at a later date.

2. INCOMING INSPECTION

After material has been accepted from the carrier, each shipment normally is examined for administrative, physical, and/or electrical discrepancies. Suggested inspection criteria include:

(1) Match packing list with purchase order to assure compliance.
(2) Validate quantity.
(3) Visually inspect parts for physical damage and proper marking.
(4) Sample check critical mechanical dimensions, if applicable.

Extensive electrical testing normally is not necessary since the manufacturer has fully tested product prior to shipment. If some electrical testing is desired, the tests should be conducted on a sample basis at room temperature (25°C). Caution is advised when testing electrical parameters because devices can be damaged and/or inaccurate data obtained by:

(1) Exceeding maximum operating temperatures with poor test procedures and/or improperly calibrated equipment.
(2) Poor test methods or inexperienced personnel.
(3) Use of different test circuits and/or conditions than used by the manufacturer.

3. CLAIMS

Administrative errors, such as discrepancies on packing lists or invoices, can best be treated by contacting the Returned Material Coordinator at the supplier.

Any decision to return product must be properly authorized in advance. Contact the Returned Material Coordinator at the manufacturer for authorization and specific return instructions. Product should be returned in the original shipping container, when possible. Receipt of *unauthorized* returns at the manufacturer's location often results in delay of resolution of invoices as well as potential loss of material and loss of time required to retest and reship. The minimum information requested prior to authorization includes:

(1) SPECIFIC REASON FOR REJECTION AND RETURN ("does not work" or "failed" is not an adequate explanation).
(2) Quantity and description (part number) of product.

(3) Original order number.
(4) Original ship date.
(5) Original invoice number.
(6) Material and financial disposition requested.
(7) Detailed replacement instructions, if applicable.

4. INSTALLATION, MOUNTING, AND COOLING CONSIDERATIONS

Before installing power semiconductors, it is important to understand why so much emphasis is placed on using proper mounting techniques. In order to obtain maximum efficiency and greater reliability in the use of power semiconductors, it is imperative that the heat developed by power dissipation at the junction be removed as fast as possible. There are usually three distinct obstacles in the path of this heat transfer: (a) interface and material between the semiconductor element and the semiconductor device mounting surface (b) interface between the device mounting surface and the heat sink (c) transfer of heat through the heat sink to the ambient, which might be natural convection air, forced air, oil, or water. These "obstacles" are referred to as thermal resistances: (a) $R_{\theta JC}$ - Junction-to-Case(b) $R_{\theta CS}$ - Case-to-Sink (c) $R_{\theta SA}$ - Sink-to-Ambient. This thermal transfer is depicted using an electrical analog in Figure 4.1.

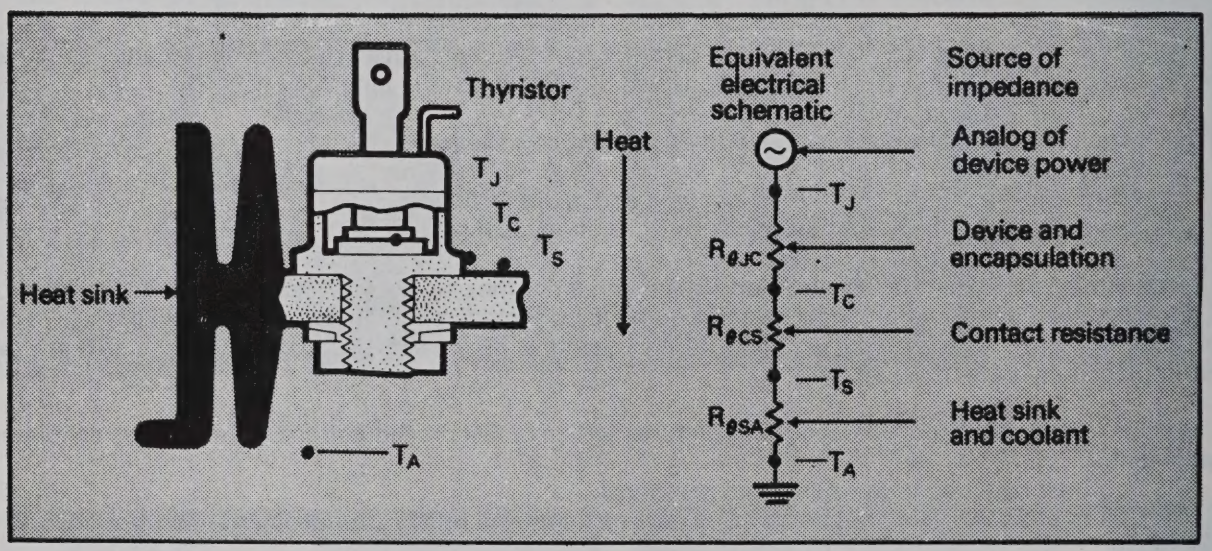


Figure 4.1 Conventional thermal circuit using an electrical analog.

The junction-to-case thermal resistance is generally a function of device construction and design and is determined by the semiconductor manufacturer. Except for disc mount devices which require the user to apply the correct mounting force to assure the proper $R_{\theta JC}$, the user has no control over $R_{\theta JC}$ once a device has been selected. The user's only option then is to select semiconductors that offer low junction-to-case thermal resistances. The other two thermal resistances, however, are quite variable, and the user must carefully consider the various methods and techniques available to insure long life and efficiency.

Primary considerations in obtaining a low case-to-sink thermal resistance are the degree of flatness and surface finish of the device and heat sink mating surfaces, the use of a thermal joint compound, and the proper amount of force (torque) applied. A complete discussion of these considerations and others are presented in the Westinghouse application data sheet "Mounting Power Semiconductors" in the General section of the Data Book. Every user is encouraged to read this application data sheet as it offers many practical suggestions on mounting and remounting all types of power semiconductors — stud mount, disc mount, flat base, etc. A couple of suggestions are worth highlighting: *Use* a torque wrench to insure proper mounting force. *Use* thermal joint compounds sparingly — it only takes a thin film between the device and heat sink mounting interface

— most people apply too much compound! Remember, when using insulating hardware, that the case-to-sink thermal resistances will increase about tenfold!

The final obstacle in the heat removal path is the sink-to-ambient thermal resistance. The semiconductor user can minimize this value by choosing the proper heat sink and most effective cooling method. A semiconductor can be no better than its heat sink! A wide range of heat sink materials, configurations, sizes, and finishes are available that will meet almost any space, cost, and heat dissipation requirement.

The most cost effective and popular air cooled heat sinks are made from aluminum extrusion. For natural convection air, aluminum heat sinks can be black anodized or painted black to optimize their ratings. For example, painting heat sinks black improves natural convection ratings by as much as 25% compared to unpainted heat sinks of equivalent size. For higher output current at less cost, forced convection is the answer. Forced air can frequently allow the user to more than double the output current of a given device/heat sink assembly over natural convection rating capability. Why buy more semiconductors than are really needed to do the job? A few fans and some baffling may provide a substantial savings in system design costs. Use forced air in lieu of natural convection air when possible.

Water cooling is the most efficient type of cooling in general use today. In order to optimize the thermal efficiency of a water-cooled heat sink, pure copper heat sinks should be used. Copper alloys, bronze, aluminum, etc. generally have much lower thermal conductivities and thus are not as efficient. Figure 4.2 shows 1000 ampere SCR's mounted on comparable air cooled and water cooled heat sinks. The water cooled assembly offers from 1.5 to 4 times more output current than the air cooled assembly, weighs only one-third as much, occupies about 40% of the space, and costs about the same. Therefore, when heat sinks are compared, water cooling (if available) is usually the most economical choice; forced convection air is next; and natural convection air is last.

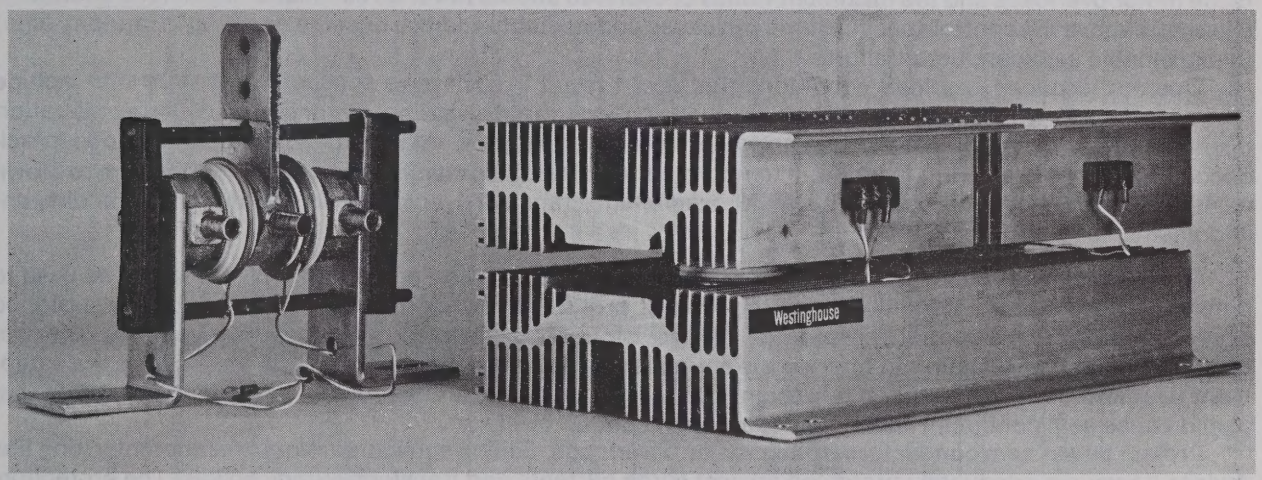

Figure 4.2 1,000A Disc SCR's mounted on comparable water cooled and air cooled heat sinks.

A final consideration when installing power semiconductors is to place them where the surrounding ambient temperature is as low as possible. Do not mount semiconductors near or above transformers or other heat generating components in a cabinet and avoid "dead air" pockets. Mount semiconductors heat sinks vertically so as to take advantage of the natural chimney-effect or up-draft of air flow. When using forced air or water to cool various components in a cabinet, make sure the cooling medium reaches the power semiconductors first. Good installation practices when mounting and cooling power semiconductors will insure good operating performance and long life.

5. OPERATING POWER SEMICONDUCTOR EQUIPMENT

There is still a tendency to consider the "state-of-the-art" in the design, manufacture, and application of power semiconductors as something new, mysterious, and glamorous. Not so! Industry has long been using

silicon power semiconductors and a vast knowledge in the use of these devices has evolved. Along with this knowledge has come a new "state-of-the-art" for using and maintaining semiconductor equipment. The emphasis placed on selecting, purchasing, and installing devices is part of it, but of equal importance is the proper use and maintenance of equipment employing power semiconductors.

Protect power semiconductors from excessive heat. Semiconductors are composed of materials having different rates of thermal expansion. Therefore, both short and long term temperature excursions not only impair the electrical characteristics of these devices, but also set up internal mechanical stresses at each of the material interfaces. These combined effects of high temperature excursions can ultimately lead to device malfunction and destruction. The maximum temperature limits of various materials used in semiconductors vary from 150°C for soft solder to 1300°C for silicon. Once these materials are combined into a fabricated device, however, electrical deterioration begins at lower temperatures.

For example, forward and reverse blocking capability of a junction begins to decrease and leakage currents increase when allowable maximum junction temperatures are exceeded. (These temperatures are generally between 125°C and 200°C, far below the maximum temperature limit of silicon itself.)

Periodic monitoring of ambient temperatures, cooling fan operation, cooling water temperatures, and case temperatures of the semiconductors themselves will pinpoint many malfunctions before they cause catastrophic failures. Because of the importance of preventing high temperatures from developing, this monitoring must be emphasized in the operating procedures for the equipment operator.

Avoid overloading equipment. Avoid overloading the semiconductor, which in effect, means protect against overloading the equipment that the semiconductors are feeding and/or controlling. For example, overloading a motor operated with semiconductor controls puts a direct overload on the semiconductors. Even if this overload is only for a short time, the semiconductor's useful life can be shortened. Controls are designed to include motor overloads and the maximum values of overload should never be exceeded. Continued short term overloads above the control specifications can cause undetectable additive damage resulting in random, often unexplainable semiconductor failures.

Operator induced overload conditions that could result in excessive semiconductor currents include high on/off duty cycle or jogging for high production needs, rapid reversing, motor jam, and long acceleration time. Some mechanical problems that can cause motor overloads are high equipment temperature due to lack of cooling, wiring or bearing failure due to improper installation or maintenance, phase failure due to blown fuses or loose connections, phase imbalance, overvoltage, transient overvoltage and contaminants or dirty environment.

Table 4.1 shows various motor stress conditions and the common protection. This table can be used to determine adverse load conditions and the type of protection that should be used. In properly designed system, overload conditions are considered and provisions are made to accommodate the overloads. The user or operator has an obligation to operate the equipment within the design ratings. The table shows the equipment user and designer methods to prevent overloading a motor, and hopefully, to avoid the situation that would cause semiconductor failure or reduce semiconductor life.

Protect power semiconductors from transient overloads. Silicon semiconductors are inherently long life devices if they are adequately protected against surge currents and transient voltage spikes. The protection against failure due to these phenomena are relatively simple and normally this protection is designed into the circuit. In industrial plant environments, most voltage transients in semiconductor circuits arise from three major causes:

Switching is the most common source. Whenever current is switched on or off in an inductive circuit, a transient voltage is generated at the switch terminals. Transformers and motor windings are highly inductive components, and the circuit wiring itself is inductive. Surges caused by lightning contribute to switching transients. These transients can originate in remote circuits and still feed back to the semiconductor circuit through the supply line. Protection of semiconductors from such transients is primarily a matter of attenuating the surge to a level the semiconductor can tolerate.

Commutation transients are associated with the reverse recovery characteristic of a rectifier junction. Since, in normal use, a semiconductor is continually switching from a conducting state to a non-conducting state, there are rapid changes of current (high di/dt). For this reason, and especially where fast switching rectifiers are used, it is imperative to keep circuit inductance at a minimum. Here again, suitable suppression networks should be designed into the circuit.

Regenerative surges in inductive or dynamic loads is the third major source of reverse voltage transients. Such loads include motors, lifting magnets, solenoids, relays, and many other devices involving stored inductive energy in the form of high induced voltage. Suppression of these transient voltages usually requires protective devices with high energy storage capacity.

Problem	Cause	Motor Current Variance	Semiconductor Current or Voltage Variance	Common Semiconductor Protection	Comments
Overload	Operators Choice	Increases three phase current approaching 200%.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	Operation at thermal overload conditions can reduce semiconductor life. Depending on the design up to 600% increases in semiconductor currents are possible resulting in reduced life or shorted semiconductors Surge currents can also reduce semiconductor lifetime and cause semiconductor failures. High ambient temperatures produce the same results as high currents i.e., reduced life and failed semiconductors. Never operate semiconductors without proper cooling.
Motor Jam	Load Blockage	High operating time at locked rotor current to 600%.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
High On/Off Duty Cycle	Jogging for High Production Needs	High operating time at locked rotor current to 600%.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
Rapid Reversing	Production Needs	High operating time at locked rotor current to 600%.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
Long Acceleration Time	High inertia slow starting loads	High operating time at locked rotor current to 600%	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
High Equipment Temperature.	High ambient temperatures. Lack of cooling.	No increase but can cause wiring and insulation failure.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
Motor Wiring or Bearing Failure.	Overcurrent, Improper Installation or Maintenance.	Locked rotor current to 600%.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload on semiconductors and motors. Design for semiconductor current overload.	
Phase Failure	Blown Fuse, Loose Connection	Decrease in current until motor core reaches saturation and current increases.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload Phase failure relay.	
Phase Unbalance	Unbalanced single phase loads on same line, poorly regulated service.	Decrease in one phase and increase in the other two phases of current.	Increases semiconductor current, eventual motor burnout can cause surge on semiconductors.	Thermal overload Phase failure relay.	
Overvoltage	High source	Slight voltage increase decreases current. Large increase may saturate core and increase current.	Decrease or increase semiconductor current.	Overvoltage relay.	Increase of currents can cause semiconductor failure and reduced life.
Transient Overvoltage	Lightning, opening inductive switches etc.	Slight average current increases.	High transient voltages across semiconductor when semiconductor is in the off position.	Capacitor-Resistor Networks, Voltraps, MOV, etc.	Short duration high transients can cause semiconductor failure.
Underload	Operators choice	Decrease in motor current.	Decrease in semiconductor current.	None	Light load increases semiconductor life.
Contaminants	Dirty environment	Causes corona	Causes corona	Clean room filters	Clean equipment periodically even with filters. Corona carbonizes dirt and causes eventual semiconductor shorts.

Table 4.1 Motor Overloads and Their Effects on Semiconductors

Some of the common devices used for transient protection are capacitors, zener diodes, free wheeling diodes, ⓦ Voltraps, and varistors (MOV/ZNR).

Protect power semiconductor circuits from current overloads. The power semiconductor circuit must be protected from heavy current loads caused by short circuits or other component breakdowns. Several methods are available for this type of protection.

Fuses — Semiconductor fuses protect against overloads and, when properly applied, remove the semiconductor from the power source when an overload occurs. However, the result is downtime and higher operating costs. Therefore, fusing is generally limited to applications where the power source can damage components before slower breakers remove the power.

Mechanical breakers — Magnetically operated breakers provide an inexpensive means of limiting current. This type of breaker operates best under short circuit conditions and offers speedy, low-cost restarting and relatively fast circuit interruption.

Thermal breakers — These employ heating elements to operate bimetallic contact actuators. This type of breaker offers reasonable protection for wires and good protection for components with high thermal capacity. Their ability to protect semiconductors is, however, limited.

Overrated semiconductors — Semiconductors with current ratings high enough to accommodate anticipated current overloads is another method of protection. This approach allows the cost of fuses, wiring, and mounting to be put into the semiconductor. It also allows minimal protection, so safety considerations require a conventional circuit breaker to disable the circuit in extreme malfunctions.

Combinations — Combining circuit breakers with fuses, oversized semiconductors, or current feedback circuits are frequently applied techniques. Another approach is using special branch protection. For example, each leg of a single phase bridge might be separately protected instead of using a single fuse or breaker for the entire converter; a motor armature circuit can be protected by a breaker, while the mains are fused. This arrangement prevents overstressing a motor while the semiconductor devices are operating at high current peaks that are within fuse limits.

Keep power semiconductors clean. Semiconductors and semiconductor equipment must be kept clean. Why? Because on high power semiconductors, the glass or ceramic seal on the semiconductor package can be a source of trouble when dirt accumulates. Even when good engineering practices are followed in the positioning of components and support material to reduce or eliminate excess voltage stress and voltage gradients, these gradients can change with moisture, dirt, pressure, temperature and aging. With a clean system, high transients can initiate corona which will then be extinguished upon return to normal voltage. However, with any accumulation of moisture or dirt on the insulating glass or ceramic surface, the corona will remain when the voltage returns to normal, and can cause extensive damage to the circuit. Even semiconductors without a visible layer of contaminants may be covered with conductive particles that can cause corona. Therefore, periodic cleaning is advisable. The time between cleanings could be lengthened by the proper use of filters, but filters will not eliminate the need for cleaning. A good maintenance program is essential to proper operation of semiconductors.

6. PREVENTATIVE MAINTENANCE

The key to successful and efficient operation of high power semiconductors is a good, well-planned maintenance program. Routine maintenance of semiconductor equipment involves putting into actual practice the good operating procedures listed in section 5 with emphasis placed on (a) temperature build-up, (b) dirt accumulation, and (c) loose mounting and/or connections. A regular schedule should be followed for checking and eliminating these conditions.

(a) Temperature build-up may be caused by excess ambient temperature, poor or blocked air circulation, failure of cooling devices, such as fans or water circulating equipment, dirty heat sinks, and air filters, or equipment overloading. Since temperature build-up is usually gradual, it should be constantly monitored with strategically placed thermocouples. A suggested method of affixing a thermocouple to a semiconductor base or heat sink is to drill a small shallow hole, fit the thermocouple into it, and then peen the surface around the hole to secure it. Equipment designed for forced air cooling or water cooling should never be energized without proper air or water flow.

(b) Dirt accumulation on the glass or ceramic surfaces of semiconductor packages must be periodically and thoroughly removed. When cleaning semiconductors, the safest cleaning method consistent with desired

results should be used. Solvents can be hazardous and should be used with care. Even a solvent that is considered non-toxic can kill or injure when used with improper ventilation. One of the safest methods of cleaning is by wiping with clean cloths. Often due to space limitations, the areas that need to be cleaned cannot be properly reached and, therefore, a liquid cleaner must be used. Table 4.2 lists solvents that could be used as cleaners.

Solvent	Fire Hazard	Explosion Hazard	Toxicity Hazard	Electrically Conductive	Attacks Rubber Insulation	Precautions
Water, tap	None	None	None	Yes	None	Rinse with distilled water, dry thoroughly
Water, distilled	None	None	None	No	None	Dry thoroughly
Water/detergent	None	None	None	Yes	None	Rinse with distilled water, dry thoroughly
Methyl alcohol	High	High	High	No	Slight	Avoid skin contact, use ventilation
Ethyl alcohol	High	High	High	No	Slight	Can cause internal damage; ingestion can cause blindness
Isopropyl alcohol	High	High	High	No	Slight	Mix with distilled water to reduce hazards
Paint thinner (mineral spirits)	Low	Low	Low	No	Slight	Use proper ventilation; limit exposure to rubber
Acetone	High	Moderate	Low	No	Slight	Limit exposure to prevent rubber degeneration
Perchloroethylene (dry-cleaning solvent)	Low	Low	Moderate	No	Slight	Use short exposure to prevent rubber damage; irritates eyes and causes headaches; heating causes fumes
Trichloroethylene	Low	Low	Moderate	No	Slight	Use adequate ventilation; limit exposure time to prevent rubber damage
Freon	Low	Low	Low	No	Slight	Use adequate ventilation; limit exposure time
Maltier XL-100	Low	Low	Low	No	Slight	Use adequate ventilation; limit exposure time
Miller Stephenson MS-180	Low	Low	Low	No	Slight	Use adequate ventilation; limit exposure time

Table 4.2 Semiconductor Cleaning Solvent Characteristics

The safest method of cleaning semiconductors, as shown in Table 4.2, is to use a detergent wash and then flush with distilled water. The system must be completely dry before the reapplication of power. Regular tap water can contain many conductive impurities and should not be used as a final rinse.

Methyl, Ethyl, or Isopropyl alcohol could be used for cleaning, but they can attack sleevings and insulations. Before using alcohol or any solvent, its use should be checked on a small sample of sleeving and insulation to determine if they are attacked. Since time of exposure to a solvent determines any adverse effects, the time of exposure during the test should be the same as the time expected during actual cleaning. Any elongation, softening or actual decomposition could eliminate the use of the solvent. A temporary softening may not be detrimental. Remember that alcohol is toxic and should be used with care.

Follow all safety precautions when using any solvents. Read the labels on all the chemicals. Do not mix solvents (or any chemicals) unless recommended. The information regarding solvents, their fire, explosion and toxicity hazards, etc., are believed to be accurate, but it cannot be guaranteed. This information is given as a general recommendation for information only.

(c) Along with scheduled periodic cleaning, a systematic checking of mounting and terminal connection tightness should be specified. If a loosely mounted device is discovered, it should be removed, both mounting surfaces thoroughly cleaned, thermal compound reapplied, and then remounted with the specified torque.

7. TROUBLE SHOOTING AND SERVICING

Properly protected semiconductor devices incorporated in well-designed circuits should last for the life of the equipment. Semiconductors should not be a major problem for the maintenance engineer. However, experience shows that up to a 10-15% failure rate can occur during equipment lifetime, due chiefly to misuse, misapplication, or neglect of the equipment and overloads caused by natural forces, such as lightning. Therefore, to operate efficiently, the maintenance department must have the proper tools and equipment. Most

of these essential items are elementary and relatively inexpensive when compared to the wide array of measuring devices and instrumentation available for the study of power semiconductors and associated circuitry. Suggested equipment for moderate service work:

1. Volt-ohmmeter (voltmeter)
2. Clamp-on ammeter
3. Probe-type temperature indicator
4. SCR/Rectifier blocking voltage test circuit (see Figure 4.3)
5. Transistor blocking voltage and gain test circuits (see Figures 4.4 and 4.5)
6. Torque wrench and complete standard tool kit
7. Oscilloscope

An oscilloscope is used for viewing the current and voltage waveshapes within a semiconductor circuit. Eventually, all technicians become familiar with a "scope". It is the most important and useful tool available to the troubleshooter.

Equipment Breakdowns and Malfunctions. What should maintenance personnel look for when equipment breaks down? Are there visual signs to indicate why a semiconductor failed? As with any other type of equipment, there is much that can be learned from one's own senses and experience. With electronics, heat is still the number one symptom of impending failure. So be alert for charred or discolored components—that is a sign that too much current flows or has flowed through the component, and if it has not failed, it soon will. Although the trouble could be limited to the failed component, it is possible that some other component is at fault through failure or misadjustment. A thorough knowledge of the theory of operation of the equipment will be invaluable in tracking down *real* causes of component failure.

Voltage related failures, on the other hand, are a bit more difficult to locate because there is usually no outward sign of failure. However, this type of failure is, more often than not, catastrophic, and shorted devices result. Shorted devices are much easier found than downgrades or control malfunctions. One of the most destructive causes of failed semiconductor components is lightning storms. The electrical forces generated by nature are enormous, so watch for equipment malfunctions during and just after an electrical storm. The maintenance engineer should also monitor closely any equipment that is pushed to its operating limit, thereby increasing the possibility of failures.

As a general procedure for checking out a suspect semiconductor, the following sequence of test checks should be performed:

(1) Look at the suspect device(s) [with the system power *off*]using a volt-ohmmeter—check for shorts.

(2) If no short exists, apply power (reduce power, if possible) and using a voltmeter or scope, check to see if the suspect device is blocking voltage.

(3) If the unit is blocking voltage, the user should then check to see whether or not any current is flowing. This current flow can be measured with a clamp-on ammeter, voltmeter in conjunction with a current shunt or resistor that is in series with the suspect unit, or a scope.

(4) Finally, the suspect unit should be checked along with the other power semiconductor components in the circuit to confirm that the devices are all operating within their maximum allowable case temperature. This maximum allowable case temperature can be determined from the manufacturer's technical data sheet by knowing the device's circuit configuration and actual current magnitude and waveform. A probe-type temperature indicator can be used for making case temperature measurements.

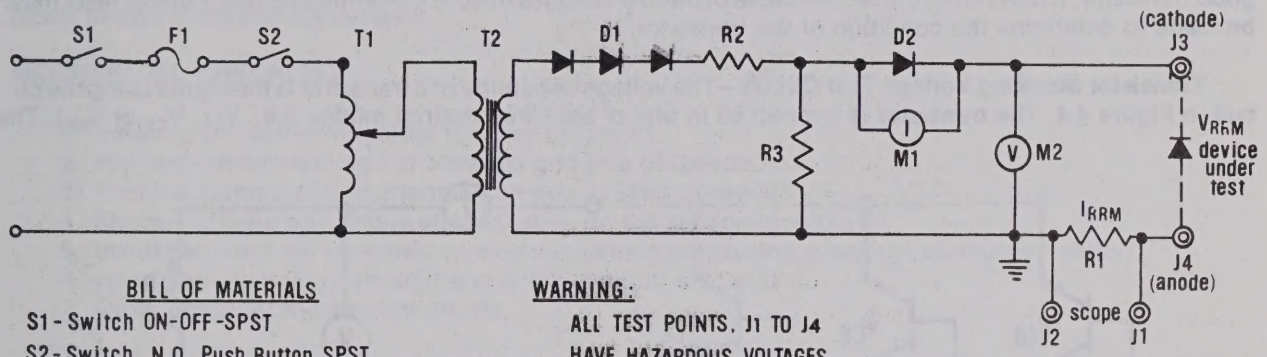
If the suspect device(s) fail any of the above test checks, the system power should be turned off and the suspect devices removed from the circuit for further test and evaluation. In some instances, the devices can be tested without the need of removal, test, reinstallation, and down time. However, the user should make certain that the measurement being taken is that of the device under test by disconnecting one power lead (also gate lead in case of SCR) for circuit isolation. Disc devices, because of their double-sided mounting, may be difficult to isolate and may have to be removed from the circuit. In this case, the disc device must be clamped with sufficient force (approximately 200 lbs.) to get a valid reading.

Rectifier/SCR Testing

Volt-ohmmeter—An ohmmeter can be used to check rectifier polarity or as a quick check to determine whether an SCR or rectifier (diode) has failed *open* or *short*. Note: An ohmmeter is *not* a valid tester for measur-

ing blocking voltage capability. If an SCR anode-cathode measurement shows a short in *either* direction or if the gate-cathode measurement shows a short in *both* directions, then the SCR is a short. For an SCR to be open, the anode-cathode measurement as well as the gate-cathode measurement must show an infinite resistance in *both* directions. Likewise, a rectifier must show zero resistance in both directions for a short and infinite resistance in both directions for an open. A rectifier normally shows low resistance in the forward direction and high resistance when the ohmmeter probes are reversed. Thus, the ohmmeter can be a check for rectifier polarity. An open failure on a Ⓦ high power SCR or rectifier is a rare event due to compression bonded encapsulation (CBE) device construction.

SCR/Rectifier Blocking Voltage Test Circuit—The following test circuit (Figure 4.3) describes a simple blocking voltage tester that is capable of testing devices up to 1800 volts and can be built for about $100.00. The



BILL OF MATERIALS

S1 - Switch ON-OFF-SPST
S2 - Switch N.O. Push Button SPST
F1 - Fuse 1.5 A, 120 V
T1 - Trans. PC8302 - Variac
T2 - Trans. T-21P89 Thordarson
D1, D2 - Diodes Ⓦ 1N5054
R1 - Res. 1.0Ω Precision Non Inductive
R2 - Res. 220 KΩ, 2 Watt Carbon
R3 - Res. 1KΩ, 10 Watt Carbon

J2, J4 - Banana Jack (Black) Johnson
M1 - Meter 0-5 Milliamp D.C. (2Ω)
M2 - Voltmeter

WARNING:

ALL TEST POINTS, J1 TO J4 HAVE HAZARDOUS VOLTAGES PRESENT DURING TEST.

SYMBOLS

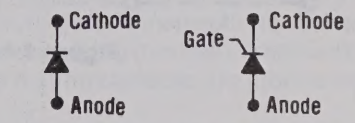

Figure 4.3 SCR/Rectifier Blocking Voltage Test Circuit

safety switch S2 must be depressed to allow voltage application and the variac controls the amount of voltage to the device under test. After each device is tested, the variac setting should be returned to zero so as not to risk damaging a subsequent device under test that might have a lower voltage rating. Never exceed the device's rated voltage when testing. Since this test is conducted at room (ambient) temperature, the measured maximum allowable leakage limit should not exceed one-half the maximum junction temperature leakage current value listed on the manufacturer's technical data sheet. When testing an SCR, the gate lead must be left open (Note: Some non-Westinghouse devices may require a gate bias termination to meet rating). V_{RRM} (reverse voltage) is measured when SCR cathode is connected to J3 and SCR anode is connected to J4; V_{DRM} (forward voltage) is measured when SCR anode and cathode terminals are reversed. The voltage is read indirectly by M2 voltmeter (V_{RRM} = 3.14 X DC meter reading). I_{RRM} or I_{DRM} leakage current is monitored directly with a scope across J2 and J1 or indirectly by M1 milliamp meter across D2 (I_{RRM} or $I_{DRM} \simeq$ 3.14 X average leakage over full cycle meter reading). For rectifiers (diodes), the V_{RRM} (reverse blocking voltage) is tested the same as an SCR. Since most rectifiers are available in standard or reverse polarity, be sure to check the polarity symbol device marking to identify the anode and cathode.

Transistor Testing

The following simple test circuits can be used for a quick check of transistor parameters but are not recommended for classifying devices. Other, more accurate, measuring equipment that has a pulsed duty cycle should be used for incoming inspection. A good curve tracer such as the Tektronix 576 will measure gain,

currents, and voltages at a pulsed duty cycle. Other, less accurate, measuring instruments, some in kit form, can be obtained from electronic supply stores for use in troubleshooting a circuit.

Volt-ohmmeter—The only valid ohmmeter measurements on transistors are short or open determinations. A shorted transistor will show a short (resistance approaches zero) in both directions across the base-emitter, collector-emitter or collector-base terminals. This test is accomplished by removing the transistor from the circuit and first measuring the resistance in one direction and then reversing the ohmmeter probes across the terminals. A good transistor will show a low resistance (conduction) in one direction and a high resistance when the probes are reversed. If any of the three tests (i.e., collector-base, collector-emmitter, or base-emmitter) are faulty, then the transistor is faulty. A faulty transistor will have either a low resistance in both directions (shorted) or a high resistance (open).

Note: This ohmmeter test is correct when it indicates a shorted or open transistor, but when it shows a good transistor, it may not be correct because of the low voltages used in the ohmmeter test. Further tests must be made to determine the condition of the transistor.

Transistor Blocking Voltage Test Circuit—The voltage capability of a transistor is measured using the circuit in Figure 4.4. The transistor is connected in one of the three desired modes (i.e., V_{CE}, V_{CB} or V_{EB}). The

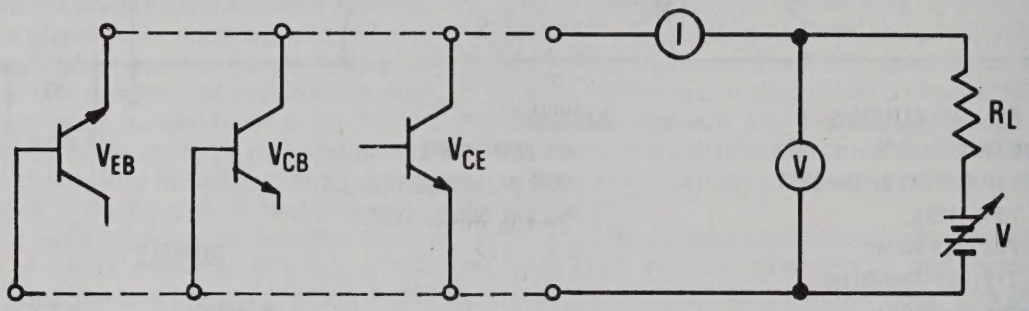

Figure 4.4 Transistor Blocking Voltage Test Circuit

current meter should be capable of 1 ma to 10 ma, the voltmeter and power supply to hundreds of volts and the load resistors should limit the current to about 10 ma if the transistor shorts. The voltage is set to the data sheet limits and the current is read. Any current reading within data sheet limit would indicate a good transistor. If a data sheet is not available then set V_{CE} and V_{CB} to the circuit voltage using 10 ma maximum as an acceptable current. When measuring V_{EB}, if no data sheet is available, set the voltage at 4 volts and use 10 ma as a maximum acceptable current.

Transistor Gain Test Circuit—Gain measurements should be made on a curve tracer or a high current pulsed test set. A D.C. gain measurement can be made if precautions are taken to limit the power dissipation and a heat sink is used. The case temperature should be monitored. A resistor to drop about 2 volts is used in the base as shown in Figure 4.5. The base voltage is slowly increased until the desired collector current is

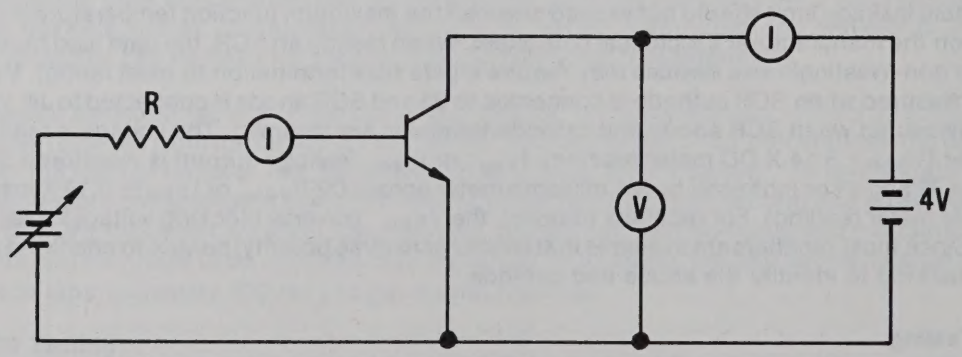

Figure 4.5 Transistor Gain Test Circuit

reached. The collector and base currents are then read. The collector-emitter voltage of 4 volts is usually used. This test is a continuous power test and should be done as quickly as possible to limit internal junction temperature. The gain (h_{FE}) is calculated as follows: $h_{FE} = I_C/I_B$

Common Causes of Power Semiconductor Failure. Most of the advice given thus far deals with the proper installation and operation of power semiconductors. However, in the event all of this advice was not followed or accidentally missed, the knowledgeable maintenance person has a good jump on discovering the reason a particular device has failed by pursuing the following checklists.

Many power semiconductor failures are the result of improper mounting and electrical application. The first step in evaluating any failure should be to assure that good engineering practices have been used in both the mechanical as well as the electrical application of the semiconductor. Faulty mechnical practices often result in eventual electrical failures.

MECHANICAL CHECKLIST

1. Torque—are semiconductors torqued properly?
2. Flatness—are mounting surfaces flat and free of defects?
3. Thermal Compound—is thermal compound used properly?
4. Stress—is there any undue stress placed on the semiconductors?
5. Insulation—are the terminals or case contaminated causing electrical conductive paths?
6. Heat Sink—is it large enough and is it clean and efficient?
7. Other pertinent mechanical details.

Torque—torque wrenches must be used, and the maximum torque rating must not be exceeded. Some semiconductors can be mechanically damaged by too much torque or thermally damaged by too little.

Flatness—heat sink must be flat, free of burrs and ridges, with holes and edges chamfered. These defects could prevent the proper seating of the semiconductor, resulting in thermal or mechanical damage.

Thermal Compound—should always be used according to the manufacturer's instructions. Either too little or too much compound could result in poor thermal impedance. When applying thermal compound, be certain that the threads remain dry. Lubricated torque specs mean that the mating surfaces are lubricated. Apply thermal compound to both sides of insulating washers, when used.

Stress—semiconductor should not be used as a support for heavy electrical leads. Lead stress can cause mechanical seal cracks resulting in hermeticity problems. Mechanical stess can also be transmitted to the junction causing cracks in the element or solders, resulting in failures.

Insulation—insulation between semiconductor terminals or terminals and case is often very small. When operating the semiconductors in moist or contaminated areas where voltage creepage can become a problem, additional protection should be used against such electrical conductive paths.

Heat Sink—should be large enough for proper heat transfer. Undersize heat sinks often cause junction temperature to exceed maximum ratings. All types of corrosion and oils should be removed with solvents or emery cloth to insure the lowest possible thermal impedance between mounting surface and heat sink.

ELECTRICAL CHECKLIST

1. Overcurrent—is current exceeding maximum ratings?
2. Overvoltage—are maximum voltage ratings exceeded?
3. Surge Current—is there a possibility of a fault that could cause a one-time surge?
4. Transient Voltage—are transient suppressors used?
5. Power—is the semiconductor operated within rated power?
6. Testing—is the testing damaging the semiconductor?
7. Specs—is the semiconductor operated within the data sheet?

Overcurrent and overvoltage—absolute maximum ratings should never be exceeded under worst case operating conditions. For reliable operation with a minimum number of failures, current, voltage and temperature should be derated. Usually the greater the derating, the more reliable the semiconductor becomes. The semiconductor manufacturer should be contacted for assistance in derating specific semiconductors. Load, component, and environmental variations (especially temperature) should be investigated as probable causes of voltage or current problems.

Surge—surge current is a fault rating that the semiconductor may see under a fault condition. This fault could happen perhaps only once in the lifetime of the equipment. Surge currents and in-rush currents should

be limited to semiconductor capability or, semiconductors with greater capability should be chosen. Since the thermal time constant of the element is small, even a very short surge current can damage a semiconductor. The surge can cause a localized (hot spot) junction temperature to be exceeded even though the case temperature is cool. These localized hot spots can result in degraded or shorted semiconductors.

Transient Voltage—should never exceed maximum rated voltages. These transients can cause a semiconductor to conduct when it should be in a nonconducting period, causing catastrophic failure. Transients that exceed the maximum rated voltage can cause a slow downgrading of the semiconductor spec. Transient protection should be used if occasional or constant transients are suspected.

Power—check power rating for current, voltage and temperature of operation. Power, voltage and current must be derated with an increase in temperature. Never exceed junction temperature even though case temperature is within spec.

Testing—never insert or remove a semiconductor from a test circuit with the power on. Never exceed maximum ratings when testing. Always use proper, calibrated test equipment.

Specification—special characteristics of a semiconductor can be specified to reduce or avoid failures. Burn-in and other hi-rel testing is available to reduce failures.

If after a thorough mechanical and electrical investigation, the user is unable to determine the cause of failure, he should contact the original equipment manufacturer (OEM) for assistance. Any unusual operating or mechanical conditions found in the above investigation, along with a history of use, should be given to the OEM for review.

HISTORY OF USE CHECKLIST

1. When was the semiconductor purchased?
2. What is the date code?
3. How many were purchased?
4. How many failed?
5. How many were installed in equipment?
6. Other history.

The history of the semiconductor's use helps in failure analysis. Was the semiconductor used previously, how much, and with what failure rate? What is the failure rate with the present group? What is the date code? Have other components been changed? What were the operating conditions at the time of failure? These types of questions help isolate a problem and result in an accurate failure analysis.

At this point, if the OEM is unable to determine the probable cause of failure for the user, the OEM can have the semiconductor manufacturer perform a failure analysis. Analysis of the failed semiconductor, along with the information collected above, should aid in a prompt and accurate diagnosis of the cause of the failure.

Semiconductor reliability is a shared responsibility among the semiconductor manufacturer, the circuit and equipment design engineer, and the end user of the equipment. The manufacturer must design and build a reliable semiconductor, the engineer must use good engineering practices when designing the equipment, and *the user must operate the equipment within its ratings and see that it is running properly and that its environment is clean. If these conditions are met, high power semiconductors will be reliable.*

8. IDENTIFICATION AND REPLACEMENT

Many semiconductors are identified by a JEDEC number. JEDEC numbers for rectifiers begin with a "1N" prefix (i.e. 1N4001, 1N1206A, etc.) whereas SCR's and transistors begin with a "2N" prefix (i.e. 2N681, 2N3055, etc.). A JEDEC number is an attempt by the industry (Joint Electronic Device Engineering Council) to standardize electrical and mechanical parameters so that products of one manufacturer will be interchangeable with those of another manufacturer. The user should, however, be careful when making a direct JEDEC substitution of another manufacturer because the JEDEC registered parameters do not always cover all of the critical parameters. As a result, manufacturers using completely different manufacturing processes often sell devices to meet the *same* JEDEC number. While this may not pose a problem in most general purpose and phase control applications, the user must recognize that various manufacturer's devices marked with the *same* JEDEC number can exhibit completely different secondary characteristics and safety margins. An engineer may have unknowingly designed his circuit around a particular JEDEC type number from a manufacturer with process A

and a big safety factor (i.e. 6 ampere rated device that really has a 12 ampere actual capability). Everything works fine until the user chooses a replacement JEDEC from another manufacturer . . . then the new devices keep failing in the circuit. Therefore, to be safe, all JEDEC substitutions should be evaluated thoroughly before use.

Most power semiconductors (especially those rated over the 40 to 100 ampere range) are marketed under their respective manufacturer's part number. Even though each manufacturer uses its own device nomenclature, the mechanical packages and electrical ratings are reasonably well-standardized throughout the industry. Therefore, second sourcing and device substitution is not difficult providing the user has a good cross reference guide and the technical data sheets for the devices being evaluated. The Westinghouse Master Cross Reference Type Number Index is located in the General section of this User's Manual and Data Book. Using this JEDEC and alpha/numeric industry index, the user can rapidly locate any power semiconductor product type number for which Westinghouse offers an exact or suggested replacement along with the page number of the corresponding Westinghouse technical data sheets. As with *ANY* cross reference guide, the user *MUST* determine the ultimate substitution acceptability by reviewing the detailed electrical and mechanical characteristic of the devices being considered. This comparison will assure that the manufacturer's suggested replacement will perform properly in the given application.

In the event that the device type number being sought is either unknown (marking is obliterated) or not listed in the Ⓦ Master Cross Reference Type Number Index, a copy of the Replacement Device Identification Checklist should be completed. Chances are Westinghouse can help identify the part and provide a direct or equivalent replacement. Simply call the nearest authorized Ⓦ distributor or local sales representative for a fast response and prompt delivery. See page 54 for checklist.

Replacement. Be sure to order the exact part number—if in doubt, include the *entire* device marking on your order. The most likely place to get "off the shelf" delivery of an exact replacement is directly from the equipment manufacturer. The OEM normally carries an ample supply of renewal parts to service its equipment market. In the event a replacement cannot be obtained from the OEM, the user should contact a local industrial or electronic distributor that handles power semiconductors. A user should only buy a given manufacturer's type number from the manufacturer's authorized distributor outlet or directly from the manufacturer's factory. To do otherwise, the user could receive inferior and/or counterfeit devices from an unknown source. Play it safe . . . deal only with a manufacturer or an authorized distributor.

The maintenance engineer must be thoroughly familiar with equipment service manuals, with the power semiconductors and their technical data sheets, and with the various tools and instruments available for testing and replacing semiconductors. It is wise to carry spare semiconductor components in stock in case of equipment breakdown—especially for critical pieces of equipment.

Many phase control applications—i.e. welding, battery chargers, DC motor controls, and general purpose power supplies can utilize rectifiers, SCR's and/or transistors with fairly broad parameters so long as the device selected has an adequate current and voltage rating and fits mechanically. The user must be *extremely* careful in selecting a replacement semiconductor when general purpose or phase control devices are used in series and/or parallel combination, when fast recovery rectifiers and fast switching SCR's are used in inverters, choppers, etc. or when semiconductor devices are marked with special (non-catalog) part numbers. Specially selected, tested, and/or matched units may be required for the semiconductor to operate properly in the equipment. Failure to use the correct semiconductor device could result in device failures, equipment damage, and plant downtime.

When selecting a device for replacement, the user can always use one with a higher voltage rating provided all other device ratings are equal or better. Likewise, a higher current rated unit can be selected so long as all of the other ratings are equal or better and the mechanical package is the same. By following these guidelines, the user can often locate a suitable replacement faster, reduce spare parts inventory by standardizing on a fewer number of replacement semiconductors, and gain increased reliability with greater voltage and/or current safety factors. Of course, the additional cost for the higher rated semiconductor must be weighed against the savings in inventory reduction, fewer failures, and reduced down time.

In the absence of any other information, a good "rule of thumb" for specifying the proper device voltage rating (based upon the supply voltage to the semiconductor equipment) is as follows: 110V line—use a 300 volt device, 220V line—use a 600 volt device, and a 440V line—use a 1200 volt device. If in doubt about what device to use, call the semiconductor manufacturer and ask for a recommendation.

The user must realize that power semiconductors, like any other component, fail for a reason. It is acceptable to just replace a suspect semiconductor if that is all that is wrong. However, frequently a suspect semiconductor fails as a result of a current or voltage overload elsewhere in the circuit. Simply replacing the suspect semiconductor in these instances will only result in destroying more semiconductors. Therefore, always look for the *cause* of failure before replacing any devices.

Replacement Device Identification Checklist

(make copy for each use)

If you have been unable to locate your power semiconductor part number in the Ⓦ Master cross reference index, simply complete a copy of this form. Chances are Ⓦ can help you identify the part and provide you with a direct or equivalent replacement. Call your nearest authorized distributor or your local sales representative for a fast response and prompt delivery.

When removing a defective semiconductor, care must be taken so as not to mar the mounting contact surfaces or damage adjacent components and to preserve all identifying device markings. It is wise to tag the smaller leads (i.e. gate, cathode potential, etc.) for ease of identification. Installing a replacement power semiconductor is discussed in the Westinghouse application data sheet "Mounting Power Semiconductors"—located in the General section of the Westinghouse Data Book. The most important considerations in remounting or replacing devices are to maintain clean mounting and contact surfaces, to continue using a good thermal compound at the mounting interfaces, and to apply the specified torque.

9. SAFETY

Safety in operating and servicing solid state equipment is especially important. Unlike mechanical equipment which has rotating parts, moving contactors, etc., there is nothing to warn one that the equipment is energized. There is also a tendency for the uninitiated to believe that voltage and current levels associated with semiconductor electronics are too low to be dangerous—*don't bet your life on it!* Obvious safety measures must be carefully observed. Most high power equipment includes built in safety interlocks to make certain that the equipment is turned off before anyone can gain access to the circuit areas.

However, maintenance personnel often defeat these interlocks to simplify their service work. This is both careless and stupid. In cases when circuits must be checked while energized there are a few simple rules which could save both personal pain and equipment damage. First, if possible, always work with another person present—one who knows how to shut-down the equipment in a hurry. Second, when working around high voltages, be sure that the floor is covered with a rubber mat, and follow the good practice of working with one hand in your pocket. This sounds simple, but it could prevent one from completing a circuit through the body. Finally, always use insulated tools to avoid short circuits that could further damage electronic components. Some of the common shop practices for safety are too often overlooked or ignored. To name a few:

1. Always wear safety glasses—hot metal from a short or a soldering iron can ruin an eye as quickly as a metal chip.
2. Keep long hair contained with a cap or net.
3. Lock out the disconnect or breaker for the circuit you are about to service.
4. Check with a voltmeter to be sure the circuit is completely dead.
5. Maintain "off limit" areas for high voltage equipment. Access should be allowed only to authorized personnel.

Too many accidents are caused by carelessness or laziness. Bear in mind that it *can* happen, so *be careful.*

Westinghouse Semiconductor Lifetime Guarantee

Westinghouse warrants to the original purchaser that it will correct any defects in workmanship or material, by repair or replacement, F.O.B. factory or, at its option, issue credit at the original purchase price, for any silicon power semiconductor bearing this symbol ✤ during the life of the equipment in which it is originally installed, provided said device is used within manufacturer's published ratings and applied in accordance with good engineering practice. The foregoing warranty is exclusive and in lieu of all other warranties of quality whether written, oral, or implied (including any warranty of merchantability or fitness for purpose).

For this you still have no second source.

5 RELIABILITY

1. UNDERSTANDING SEMICONDUCTOR RELIABILITY

Explanation of reliability. Much has been written about reliability, and it usually ends up in mountains of charts, tables, graphs, curves, and equations which require a mathematical background plus several good courses in statistics to understand. Of course, a great deal of reliability is expressed in statistical terms, such as AQL (Acceptance Quality Level), LTPD (Lot Tolerance Percent Defective), MTBF (Mean Time Between Failures), etc. It will be the object of this section to discuss reliability so that the user, the supplier, the purchasing agent, the salesman and the engineer can understand just what is required and what can be supplied in terms of a reliable product, and to what degree, and at what cost.

The age old requirements of a good newsworthy article are: Who, What, Why, When, and Where. Then, to make this a technical discussion, we add the word, "How".

The *Who* in reliability must refer to the manufacturer. Is the manufacturer dependable? Does back-up data and a good "history" of product usage in the field exist? Can the manufacturer speak knowledgeably in the realm of reliability? These things must be considered when an MTBF figure is discussed or when an LTPD value is specified.

Next, we come to the big question: *What* is Reliability? The dictionary describes it as "worthy of confidence; trustworthy." From the word rely, "to depend on; trust; repose confidence upon". This is all quite graphic and needs no further explanation. However, another parameter enters the picture here and that is the *degree* of reliability. It has become customary in the semiconductor industry to refer to any device which is a cut above the standard as a Hi-Rel device, no matter how reliable (or unreliable) the standard product is or to what degree it has been improved. So now it becomes necessary to define degree or level of reliability required and to do so in a universal language which will put us all in the same ball park. For this reason we turn to the common denominator of statistics.

In the field of semiconductors, the standard for quality has been set by the military, and rightly so, since in many of their applications life itself depends upon the *reliability* of the device being used. The basic document is Specification Mil-S-19500, "Semiconductors, General Specifications For." This specification provides an excellent table for evaluating or planning device reliability. Table 5.1 provides a sampling plan for testing a lot of devices with a reasonable assurance (90% confidence level) that, 9 out of 10 times, the number of defective units that may be found in the lot (regardless of size) will not exceed the percentage indicated by the chosen LTPD number. As an example, let us assume that a certain lot of units has been processed to meet an LTPD of 10. From the table we select a test sample of 38 devices, which allows one failure (a = 1). This would be an actual failure rate for the test sample of 2.63%. The difference between 10% and 2.63% takes into account a statistical probability of picking out defective units in the same proportion as they may appear in a lot, with a small random sample. Note that the larger the sample the greater the percent defective allowed; if we select a sample size of 326 (in the 10% column), the acceptance number is 25. This gives an actual percent defective in the test sample of 7.67%. In other words, if we continue testing the entire lot the acceptance number approaches 10%. This means that if the acceptance number is not exceeded in the first test sample (usually small), one may be sure (90%) that the number of defective units in this particular lot (one manufacturing run) will not exceed the LTPD to which we are testing. Usually, the actual quality of a group of devices is much better than is indicated by the LTPD to which they have been tested, for the simple reason that a manufacturer cannot afford to process devices to the exact degree where each test sample will produce the allowable number of defectives and no more. A rejected lot can be very expensive. Note also that, as data accumulates in "small sample" testing, the better the overall LTPD becomes.

In the example just cited, if a lot is tested to an LTPD of 10 with a sample size of 38, the lot is accepted at this level (10% LTPD) with one reject. If 10 lots in a row are accepted, each with maximum allowable failures, the total sample size becomes 380 and the acceptance number is 10. From the table this would indicate (by extrapolation) an LTPD of 3.7 for the total product. It is evident that a product with a history of lot acceptances must be considered more reliable than a similar new product, even though both are tested to the same specifications and at the same level; hence, there is a definite resistance to change by users of proven semiconductor products, even though the manufacturer has devised numerous tests to show that the product has been improved. Another reason for this "resistance" is the fact that very often changes in product are instituted for

Max. Percent Defective (LTPD) or λ	50	30	20	15	10	7	5	3	2	1.5	1	0.7	0.5	0.3	0.2	0.15	0.1

TABLE 5.1 LTPD sampling plans 1/ 2/

Minimum size of sample to be tested to assure, with a 90 percent confidence, that a lot having percent-defective equal to the specified LTPD will not be accepted (single sample). 1/ Sample sizes are based upon the Poisson exponential binomial limit. 2/ The minimum quality (approximate AQL) required to accept (on the average) 19 of 20 lots is shown in parenthesis for information only.

the sole purpose of cost reduction; then the change is made on an "as good as" basis, and only a similar history of successful usage will convince a user. In this respect, the market is often fickle because it forces many reliable manufacturers to compete with "junk dealers" on price alone, and then it pays a high price to have reliability processed into the device.

In spite of this resistance to changing an established product, it is necessary for a manufacturer to keep abreast of the state-of-the-art and, as is usually the case, an old (and proven) line of devices must be discontinued in favor of the new before enough data has been accumulated to call it equivalent. In these instances, one has to use a "projected" failure rate rather than an actual failure rate. As an example, if we take the factual LTPD of 3.7 as determined above and go back to the Table (by extrapolation), we find that we may expect one failure in 111 units; if the test is a 1000-hour operation life test, we may now say that the product has an established MTBF of 110,000 hours. For the new product, we claim the same MTBF, on the basis of starting with the same test level and including enough processing to give a reasonable assurance that the succeeding lots will pass operating life test. This is considered a projected MTBF. When the LTPD figure is applied to 1000-hour life tests or LTPD per thousand hours, it becomes the life test failure rate, (Lambda), which is expressed as percent defective per 1000-hour operation.

To sum up what is meant by reliability in semiconductors, we find that:

- The degree of reliability must be defined; the term "hi-rel" device is meaningless by itself.
- Degree or level is defined (usually) by a Mean Time Between Failure figure, along with a given confidence level.
- There is a distinction between High Reliability and Established Reliability. A device may be designed for High Reliability, but Established Reliability is achieved only from actual data covering hundreds of thousands of device hours of actual use.
- A good yardstick for estimating a "projected reliability" is the LTPD figure to which the device lot is tested, as set forth in the Table of Mil-S-19500 with a 90% confidence level.

Why is so much emphasis being placed on reliability? As semiconductors are being designed into more complex and sophisticated equipment, it becomes more and more essential to avoid "down" time or malfunctions. Also, in the missile and space program, "expected" failures cannot be tolerated. Although the greatest Hi-Rel requirements are found in such applications as aircraft, military and space projects, the equipment manufacturers and industrial users are beginning to demand more reliability in the semiconductors which they use. Here again, the cost of replacing a component must be weighed against the cost of procuring a sufficiently high reliability device to minimize or eliminate the need for replacement. This becomes our *when* of reliability; when the cost of processing a manufactured lot of semiconductors is attractive when compared to a possible malfunction of a standard device, or when the added reliability of a piece of equipment enhances the manufacturer's reputation for dependability.

Where is reliability introduced into a device—from beginning to end. It starts with the choice of suppliers of component parts and continues with incoming inspection, in-line processes and controls, processing after construction, end of line screening and testing, quality assurance testing, storage and marking methods and controls, and shipping tests and it ends with the user's incoming inspection and application with special emphasis on conformance to the parameters as set forth for the device.

This method of using actual test failures, together with a history of (accumulated data) similar devices, to obtain a projected MTBF is probably an over-simplification, but it does provide a ball park figure which, if anything, would be conservative. No matter what complicated and time consuming system is used, the results will still be an approximation.

How to achieve reliability.

How is this "extra" reliability to be obtained? We have often heard it stated that one cannot test quality into a product. This is very true; however, we can process non-quality out. First, let us consider some of the possible causes of semiconductor failure, not necessarily in order of importance:

- Excessive junction temperature
- Thermal fatigue
- Aging
- Poor construction, misalignment of parts
- Foreign particles
- Mechanical stress
- Lack of hermeticity

- Inconsistencies in crystal, doping, element
- Improper curing of junction coating
- Improper use—nonconformance to limiting parameters assigned to the device

No doubt there are many other causes of failures, but these are the ten most obvious. Many of these "faults" can be greatly minimized by rigid incoming inspections and constant monitoring of fusion furnace temperatures, etching processes, assembly practices, soldering temperature, junction coating and curing, and visual inspection up to encapsulation. This in-line control is essential for good reliability in a product and is a "must" if we are to maintain a reasonable confidence level. However, even the best controls cannot enable one to predict the effect of electrical, mechanical, and environmental stresses upon a device. For this reason, various conditioning procedures have been developed to simulate some of the above listed causes of failure. It is an attempt to prevent and/or weed out devices which may be subject to "infant mortality"-that is, failure in the first week or two of operation. It has been found from experience and many thousands of hours of operation that once a semiconductor survives the first week or two of operation,its chance of reaching the expected lifetime is more than doubled.

Normally, one would believe that with exacting in-line controls, such faults as misalignment, foreign particles, hermeticity, and improper curing would be eliminated, but this is not so. Many things can happen to a device during the encapsulation procedure which usually involves heat stresses from welding and soldering temperatures and mechanical stresses from pressures on the internal lead and pinch-off and crimping operations. Also, the amount of in-line controls must be dictated by the quality and cost required to meet competition in the volume market. Once this criterion is met, we start considering the various procedures for producing a high reliability product. There are three major contributing factors in planning a Hi-Rel program: (a) Level of reliability required; (b) Cost of achieving the required level of reliability and (c) Volume—number of units to be processed. Naturally, the customer wants the most reliability for the least cost and the customer must decide what level can be tolerated. Before going into the various levels of reliability, it would be wise to look into the various tests and procedures that are available to achieve these levels and to consider the good and bad features of each.

1. **Temperature Cycling:** Cycles from minimum to maximum rated junction temperatures and back again in a specified time. This operation is done on a batch basis and is relatively inexpensive.It is designed to weed out those devices that may have a tendency to fail due to expansion and contraction of the various materials in the device package which could crack an element or break a solder connection.
2. **Stabilization Bake:** A bake at the maximum rated temperature. The purpose of this step is to stabilize the device by further curing of the junction coating. This is also an inexpensive procedure. These first two steps are essential before proceeding with further processing. In many instances, especially in the case of military products, it is included in the standard procedure.
3. **X-Ray Examination:** A very expensive operation, made more so because of the elaborate requirements of some semiconductor X-ray specifications which require that all devices be serialized. Film must be processed and examined and careful lot control maintained so that corresponding units and film are shipped together. The equipment is expensive and the operators must be well-trained. This is the only way, however, by which faulty construction or the presence of foreign particles can be detected after encapsulation. The test becomes much more effective if performed after shock and/or vibration tests. Needless to say, the sooner this procedure can be changed from a 100% basis to a sample basis without jeopardizing the confidence level,the happier all concerned will be.
4. **Operating Life:** Perhaps the best single process for improving the reliability of a device. This process consists of actually operating the unit at stated parameters for a specific period of time. Usually, the operating conditons are the maximum rated forward current, reverse voltage, and case temperature. Times vary depending on need. This operation is expensive because every device must be handled separately, it ties up life test equipment for long periods, and scheduling times are often prohibitive. The cost of building special equipment for any particular order is also prohibitive. For this reason, volume and delivery requirements are important considerations in using this procedure.

   The reason Operating Life is so highly regarded is graphically illustrated by a Failure Rate versus Operating Time Curve, Figure 5.1. This curve falls very steeply during the initial operating time, then gradually levels out to the inherent value for the device.
5. **Blocking Life:** This process has the rated peak reverse voltage (either full or half wave rectified) applied to the units while in an ambient equal to the maximum rated junction temperature for a determined time period. This is often done in conjunction with Stabilization Bake with a moderate increase in cost because a connec-

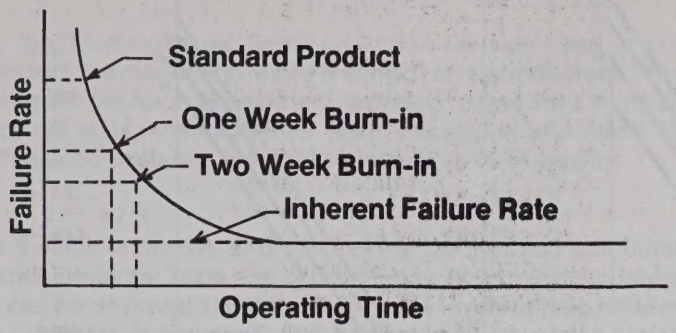

Figure 5.1 Effect of operating life burn-in on semiconductor failure rate over time.

tion must be made to each device, which then limits the number of devices that can be handled at one time. It is no longer a "batch" operation. Blocking Life is a very good alternative for Operating Life.

6. **Power Cycling (Thermal Fatigue):** The Power Cycling test may also be used as a substitute for Operating Life. However, care must be taken as to the number of cycles specified for conditioning because this is a severe test and probably reduces the actual lifetime of the device. The test consists of heating the device up to its operating case temperature by the application of forward current and then force-cooling it back to approximately room temperature. The device under test is subjected to a continuous expansion and contraction of materials which sets up stresses in the soldered and brazed connection within the device package and simulates, in an accelerated manner, the effects of actual usage. Reverse voltage is usually not applied during this test. Here again, a great deal of equipment is involved, depending on the quantities (and size) of units to be conditioned. The equipment is not very complicated and should be relatively inexpensive when compared to operating life test equipment.

7. **Monitored Shock and Vibration:** Used to determine the mechanical stability of the device. The units are subjected to specified vibrations and /or shocks while in an operating state. The current, either forward or reverse, is monitored to detect instantaneous opens or shorts or electrical "noise". This is a slow, therefore expensive, test since only a few units can be processed at a time. When this procedure is called for, it should be done before X-Ray and Hermeticity tests.

8. **Hermeticity Test:** This test is used to determine the effectiveness of the package seal which protects the element. The entrance of damaging contaminants will reduce the effective life of a semiconductor, hence, a good package seal is imperative in a high reliability device. This is a fairly expensive test when done on a 100% basis. It requires a good commercial tester and is not a batch operation.

Of these procedures, you will note that 1, 2, 4, 5, and 6 are conditioning processes, while 3, 7, and 8 are selection or "weeding out" type of tests. Naturally, any conditioning should be done before the selection tests. The monitored shock and vibration tests can be considered as both conditioning and selecting, and should be performed before hermeticity tests or X-Ray.

All of these procedures become more effective when accompanied by limitations on changes in characteristics, that is, maximum allowable ΔV_F and ΔI_R. This assures a more stable end product but may also eliminate a lot of good devices and prove quite expensive.

After a lot of semiconductors has been stabilized and most of the "weak sisters" removed by some combination of the above mentioned procedures, there is a final process which will enhance reliability tremendously and that is "derating" the device in some (or all) of its parameters. For instance, an 800 volt, 12 amp at $T_C = 150^0$ C rectifier will be more reliable if rated as a 600 volt device and even more reliable as a 600 volt, 6 amp at $T_C = 125^0$C device. The intended application of the rectifier would dictate which parameters should be derated for the best results. If the unit may be subjected to high transient voltages, then the voltage should be derated. If the unit is to be used in a circuit with frequent on-off operations or subjected to many temperature excursions, then the current and/or temperature should be derated.

To illustrate to the semiconductor equipment designer and user the value of derating as a reliability tool, graphs of the failure rates per 1000 hours for thyristors, transistors, and rectifiers are shown in figures 5.2, 5.3, and 5.4.

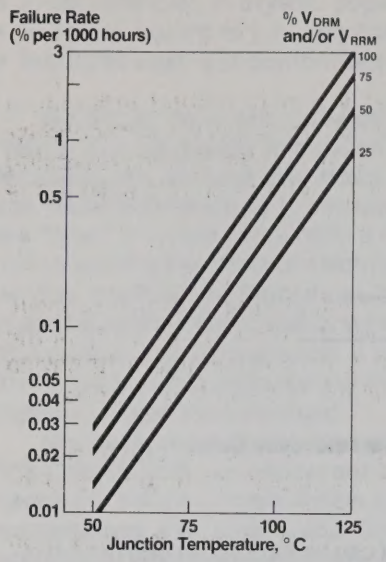

Figure 5.2 Estimated degradation failure rate for thyristors at less than 50 amps per μsec. For catastrophic failures, use 10% of these values.

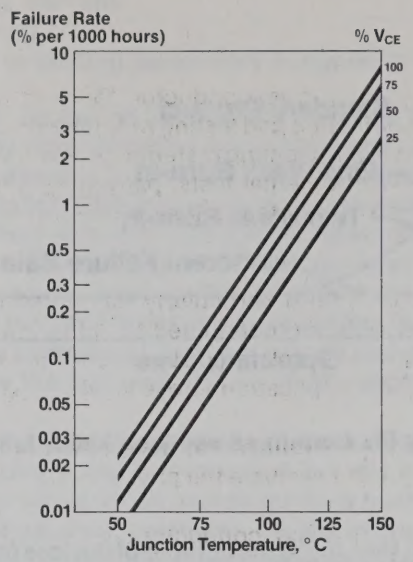

Figure 5.3 Estimated failure rate for transistors. For catastrophic failures, use 10% of these values.

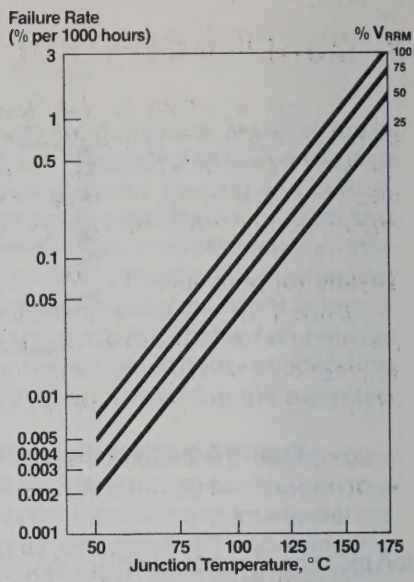

Figure 5.4 Estimated failure rate for rectifiers. For catastrophic failures, use 10% of these values.

These graphs show that one key to enhancing reliability is derating. Derate any of the reliability sensitive parameters, such as the temperature and the voltage to which the semiconductor is subjected, and derate the related parameters of current, power, thermal impedance, and time, and the reliability will be increased. A study of the derating curves shows that a reduction of the junction temperature gives a larger reduction in the failure rate than a similar reduction in applied voltage. Also, a larger percentage of failures is expected at 100% of rated voltage than at a lower (derated) voltage. Using figure 5.2, the failure rate for 125°C and 100% rated voltage is 3%. If the voltage is lowered to 75% of rated value and the junction temperature is decreased to 75°C, the failure rate is 0.15%, or 20 times lower.

This discussion has endeavored to reduce the complicated business of semiconductor reliability, whether achieving, proving, calculating or projecting, to a few undeniable truths, as follows:

- The chief reasons for unreliability must be recognized and dealt with.
- There are only a certain number of processes or procedures that can be applied to a semiconductor device to enhance its quality, once manufacturing is completed.
- There are so many variables in both the manufacture and use of these devices that each type has an inherent degree of reliability which cannot be improved upon with any amount of processing.
- Because of economic and practical considerations, one must sample test to determine and project reliability. Use of Table 5.1 provides a good method for this.
- Expense must be balanced with need in specifying a degree of reliability. Reliability can be a practical thing; it does not have to be a tool for statisticians, nor does it require exotic computer programming.

So let us keep in mind, whether buying or selling reliability, that a Hi-Rel product is a good thing, but the degree of reliability must be handled intelligently. We do not want to waste money, but we do want a device we can depend on—a reliable device.

2. QUALITY CONTROL

To insure reliability, the Westinghouse Semiconductor Division uses a quality control program, a statistical method that monitors the manufacture and testing of semiconductors. The quality of a semiconductor is determined by quality controls, such as incoming materials inspections, control of the silicon processing and chemical purity, electrical tests, environmental tests, packaging and many other controls used in the manufacturing process. These controls are inserted to insure uniform quality.

Testing for reliability

During the design of a semiconductor, and particularly before final manufacturing approval is given, operating, storage, and environmental tests are conducted to determine the integrity and reliability of the semiconductor. The tests can be operated at accelerated stress levels to help determine margins in the device design and to predict the reliability at low application stress levels. A partial list of these tests follows:

- Centrifuge, shock, and thermal shock are evaluated to determine the mechanical features of a design.
- Operating and storage life tests are used to evaluate the physical and chemical stability of the semiconductor design.
- Current surge data is gathered to verify the semiconductor current handling capability and the short, high current capability of the internal connections.
- Thermal fatigue data is used for checking element mounting integrity.
- Thermal impedance measurements are made to insure proper junction temperature during operation.
- Blocking life tests are used to determine if reliability is affected by junction temperature and voltage.
- Step stress testing can be run to show the threshold of failure and the accelerated stress areas such as junction temperature, voltage or environment.

During the manufactured life, a family plan of testing determines if the reliability test results are still valid. The goal of the family plan is to achieve maximum device yield economy consistent with sufficient assurance that end-of-life limits will not be exceeded during the semiconductor equipment lifetime. These results can be used as an interpretation of the reliability of similar device families. Other voltage and current parameters can be extrapolated from similar device characteristics.

Improved reliability is achieved through many corrective actions involving the design, process, fabrication, material, and device assembly inspections. Before any of these are changed, the reliability impact is studied and appropriate testing is instituted. Over the years, there have been improvements in the element surfaces, the element material, and the packaging that have resulted in generally lower failure rates.

Testing to determine the quality of the semiconductors is done on various parameters. This testing is repeated many times as the semiconductor element continues through the manufacturing cycle and is repeated again when the element is assembled in a package. Reliability testing, such as blocking life, is done on a sampling basis in the element state, as well as in the completed package. Surge capability and thermal impedance are used as reliability measurement tools.

Types of failures

Quality is closely related to reliability, which in turn, is dependent on failure rate. There are three types of semiconductor failures: the early or freak failures, the chance failures, and the wearout failures. These failures are shown in Fig. 5.5 in relation to semiconductor lifetime.

Early failures result when semiconductors have some production defect, material defect, or other deficiency. Even with good quality control, semiconductors will always have a small percentage of early failures, but these can be eliminated by doing quality conformance testing on all the units or by sample testing. One or more of the following tests, which could take from 2 hours to 168 hours or more, could be chosen: stabilization bake, operation life, or blocking life. Tests that are not time dependent could include temperature cycling, salt spray and hermeticity.

Wearout failures are practically non-existent in properly applied semiconductors during the normal life of a system. Where they do occur, wearout mechanisms exist both in structural flaws and in internal encapsulated contaminants. Because semiconductors cannot be made completely free of these flaws or contaminants, early failures can happen. But in well-designed, properly applied semiconductors, the wearout should occur long after the useful life of the system itself.

Chance failures occur between the early failures and the much later wearout period. This is the long period of useful life of a semiconductor during which there is small expectation of failures. The failures that do occur are time, temperature, current, and voltage dependent.

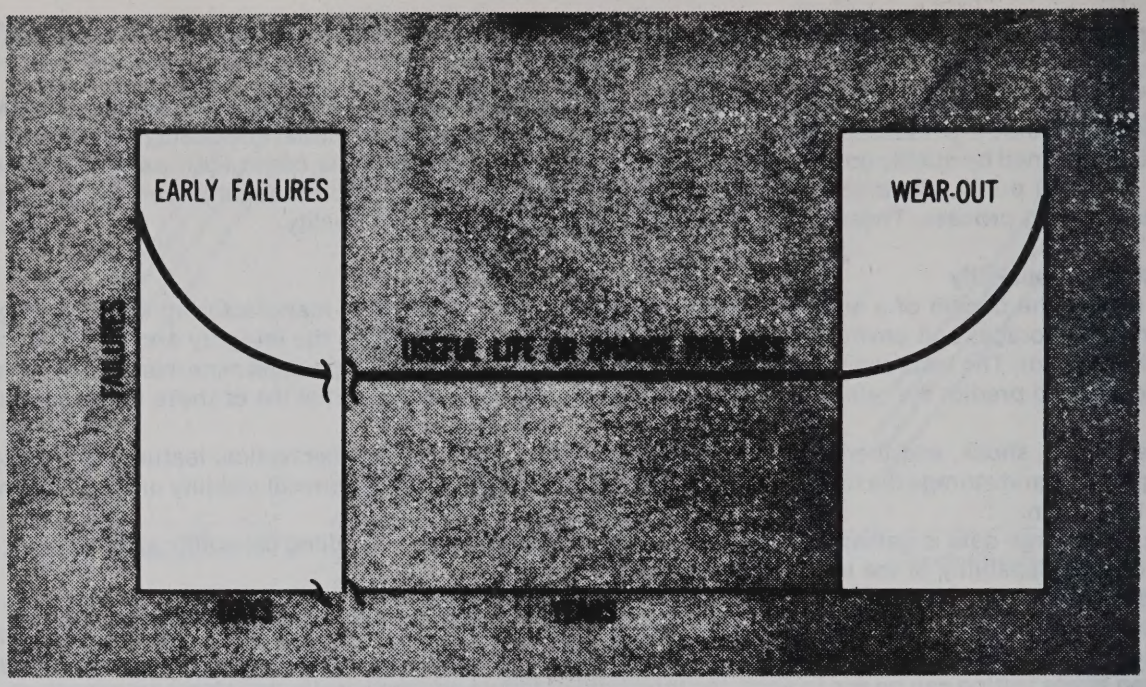

Figure 5.5 The probability of failure as a function of semiconductor lifetime.

Quality and reliability testing defined

Testing for quality and reliability is usually divided into four catagories; Group A, Group B, Group C, and Special.

- **Group A** includes all the standard electrical tests required to assure that a semiconductor meets the voltage, current, switching times, control functions, etc. as stated in the device specification. Group A is performed on every lot.
- **Group B** testing provides assurance that the semiconductor is properly constructed, durable, and will operate under extreme environmental conditions. These tests include operating life tests, stabilization bake, hermeticity tests, humidity, shock and vibration, etc. Once a manufacturer has established a consistent parts supplier and fabrication cycle, group B testing (which is expensive) may be performed on combined lots or alternate lots.
- **Group C** testing, in essence, checks whether or not the semiconductor is properly designed to meet certain special criteria. These tests include such things as high altitude test, salt atmosphere test, and thermal resistance tests. Usually, these tests are necessary only when there is a change of material, design, or process in the manufacturing cycle.
- **Special testing.** In some instances, a customer application puts unique stresses on semiconductors so that extra testing of certain parameters, or even specially designed testing, is required to assure that the semiconductor will perform as required.

Table 5.2 on page 65 illustrates a typical test plan and preferred order of grouping as recommended in Mil-S-19500.

3. RESPONSIBILITIES

User responsibility: The user has the responsibility of insuring proper operation of the equipment. The maximum rating of the equipment must never be exceeded. The voltage and current must never be raised above maximum ratings to increase production. The cooling system must be monitored periodically to insure proper cooling at all times. The semiconductors and associated equipment must be kept clean. It is imperative to reliable operation that a schedule be set up for cleaning, tightening connections, etc. In short, exercise good operating and maintenance procedures.

Shared responsibility: Semiconductor reliability is a shared responsibility among the semiconductor manufacturer, the original equipment manufacturer (OEM), and the end user of the equipment. The manufacturer must design and build a reliable semiconductor, the OEM must use good engineering practices when designing the equipment, and the user must operate the equipment within its ratings and in a clean environment. If these conditions are met, power semiconductors will be reliable.

Failure analysis as a reliability tool: Failure analysis involves the gathering and analyzing of all possible information about the cause of a failed semiconductor. Knowing the reason for failure, the user can modify the circuit to eliminate any repetitions of this failure mode, or the manufacturer can take corrective action in device fabrication or testing. Proper analysis may determine if a failure is due to voltage, current, over-temperature or surge. However, a failed semiconductor may show more than one mode of failure; a history of the use of the device is then necessary. For instance, if the installation was trouble-free until a certain point in time, when new or different equipment was added or a new operator was being trained, the problem may be easily resolved. Thus, failure analysis can often be specific and give the actual failure mode but, just as often, the actual cause of failure is masked, and help in the form of historical data is needed. A "burn-out" of a semiconductor is often violent enough to mask out much, if not all, of the original cause of failure. So, the more background furnished, the more meaningful the analysis. A good failure analysis will determine the reason for failure and corrective action can then be taken.

6 MANUFACTURING Ⓦ POWER SEMICONDUCTORS

1. FACILITIES

The Westinghouse Semiconductor Division facility (Figure 6.1) in Youngwood, Pa. is the most modern high power semiconductor manufacturing plant in the world. At the Youngwood facility, nestled in the foothills of the Allegheny Mountains, the silicon elements which house all the electrical characteristics of the power semiconductor component are made. This single location for element production extends its capability for supplying superior high power semiconductor devices to identical assembly facilities in Le Mans, France (Figure 6.2) and San Juan, Puerto Rico (Figure 6.3) with a new facility opening in Brazil to serve the Latin American market.

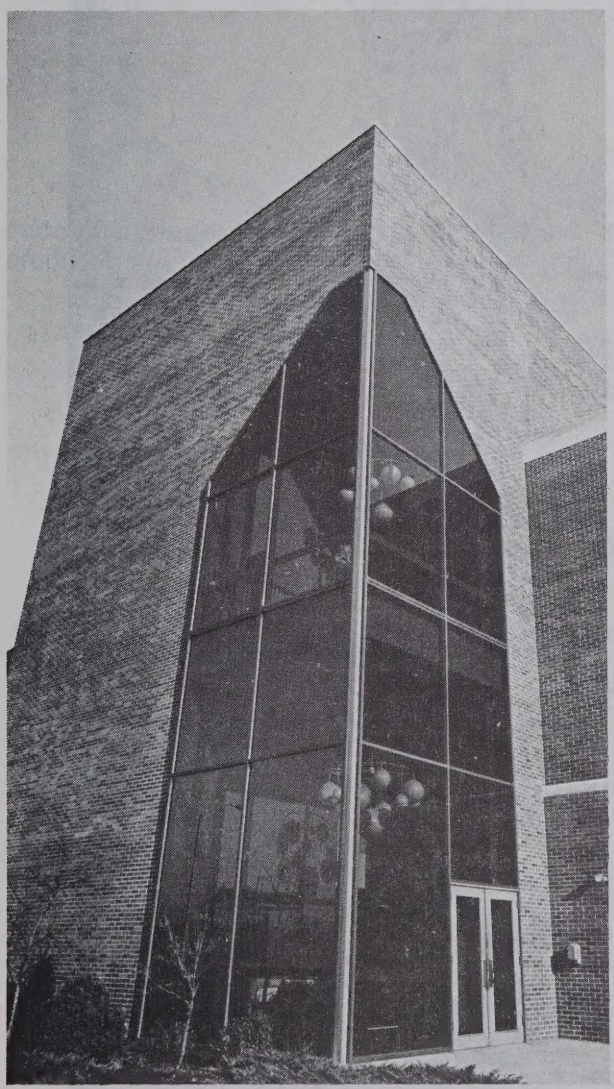

Figure 6.1 Westinghouse-Youngwood, Pa—employing the most modern, up-to-date techniques in high power semiconductor manufacturing.

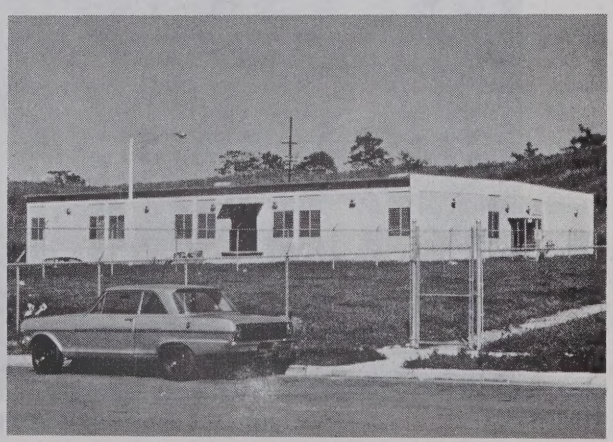
Figure 6.2 Westinghouse, LeMans, France—power semiconductor manufacturing in Europe.

Figure 6.3 Westinghouse, Puerto Rico—power semiconductor assembly in Gurabo (San Juan).



2. PRODUCT BREAKTHROUGHS

Several product breakthroughs have been instrumental in making the Ⓦ manufacturing concept a reality. One key to success is the ability to manufacture, test, and store the semiconductor element independent of the device package. First, element sizes have been standardized for rectifiers, SCR's and transistors. Comparable semiconductor element sizes for Ⓦ high power rectifiers and SCR's are shown in Figure 6.4. The early process-

ing stages for slicing and diffusing the silicon are identifical for rectifiers and SCR's. An all-diffused process for making rectifiers and SCR's offers good reproducibility and process precision. All Westinghouse high power SCR designs feature center-fired, di/namic gate structures for fast turn-on capability, high repetitive di/dt capability, and low switching losses. This gate structure is comparable to a device built with a pilot SCR to turn on a main SCR (Figure 6.5). Westinghouse developed a special di/namic mid-gate SCR for high peak

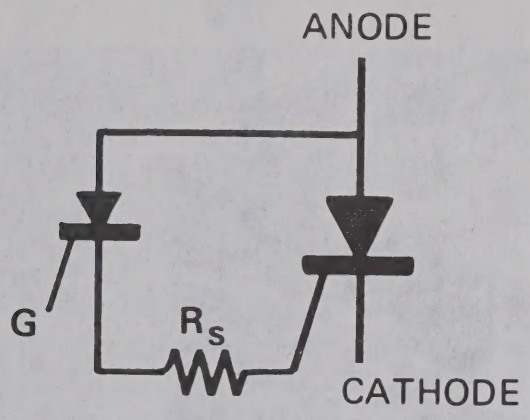

Figure 6.5 Equivalent electrical circuit for the di/namic gate design.

current and narrow pulse width fast switching applications. By using an irradiation process (see Figure 6.6) to produce fast recovery rectifiers and fast switching SCR's, Westinghouse has the advantage of being able to

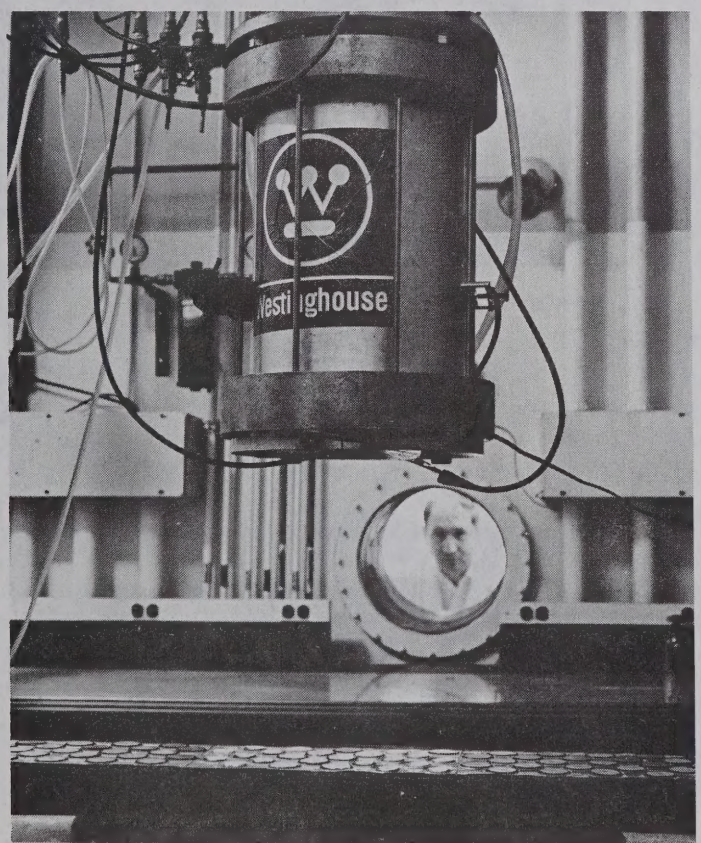

Figure 6.6 Exclusive Ⓦ irradiation process for manufacturing Fast Switching SCR's and Fast Recovery Rectifiers.

apply this technique after the semiconductor element has completed its processing cycle. This process promotes greater manufacturing flexibility and better control in producing fast switching and fast recovery characteristics. Westinghouse's special emitter shunt designs make possible dv/dt capabilities of 300 to 1000 volts per microsecond—the highest available in the industry. Exclusive Ⓦ processes for passivating semiconductor elements, enabling sealing and stabilization of the elements with no danger of degradation, complete the element breakthroughs necessary to establish a World Element Bank (Figure 6.7)—an inventory center for storing completely tested and passivated elements.

Figure 6.7 The World Element Bank, an inventory center for storing completely tested, passivated semiconductor elements, ready for assembly anywhere in the world.

Originally, power semiconductors were offered only in stud mount packages. Later, by placing the same element in an integral heat sink package, (Figure 6.8), a 40% improvement in current rating was obtained

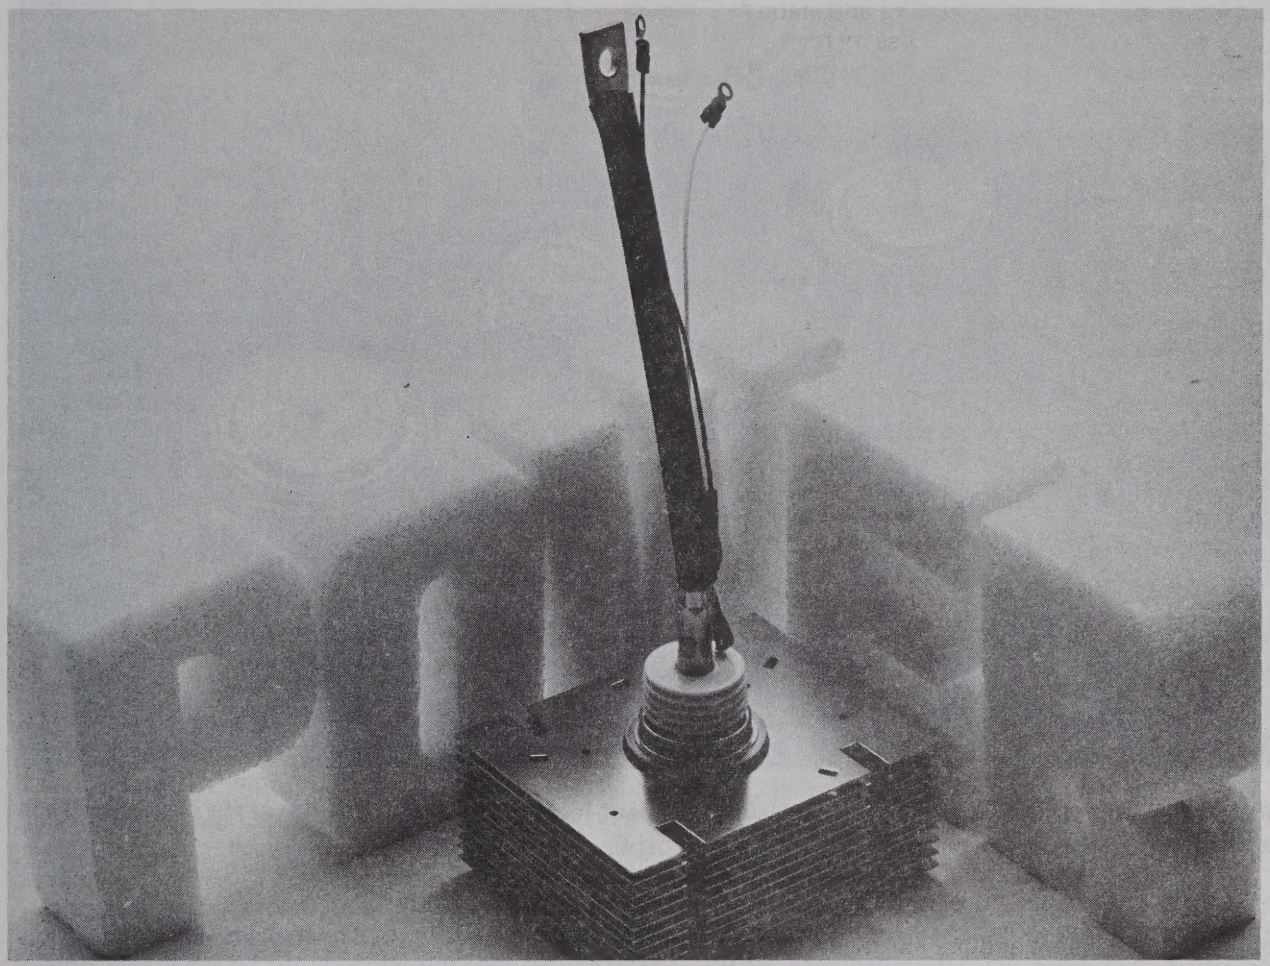

Figure 6.8 An integral heat sink package offers up to a 40% improvement in current rating over the same element size in a stud mount package.

because one thermal interface (case to sink) was eliminated. However, the real innovation in packaging was the disc; with double-sided cooling (Figure 6.9), the same element offers up to an 80% improvement in current rating over the same element in a stud mount package. An additional benefit is that it is easy to stack these disc devices in a series arrangement or a back-to-back arrangement and devices can simply be "flipped over" for reversing polarity. Initially low power semiconductor elements were bonded to the device package with a low temperature or soft solder. Later, hard solder or high temperature soldering techniques were used, and they improved device thermal cycling capabilities by an order of magnitude. However, as element sizes increased and applications became more severe, a more fatigue-free construction was required and compression bonded encapsulation (CBE) was developed. This CBE technique completely eliminates solder connections

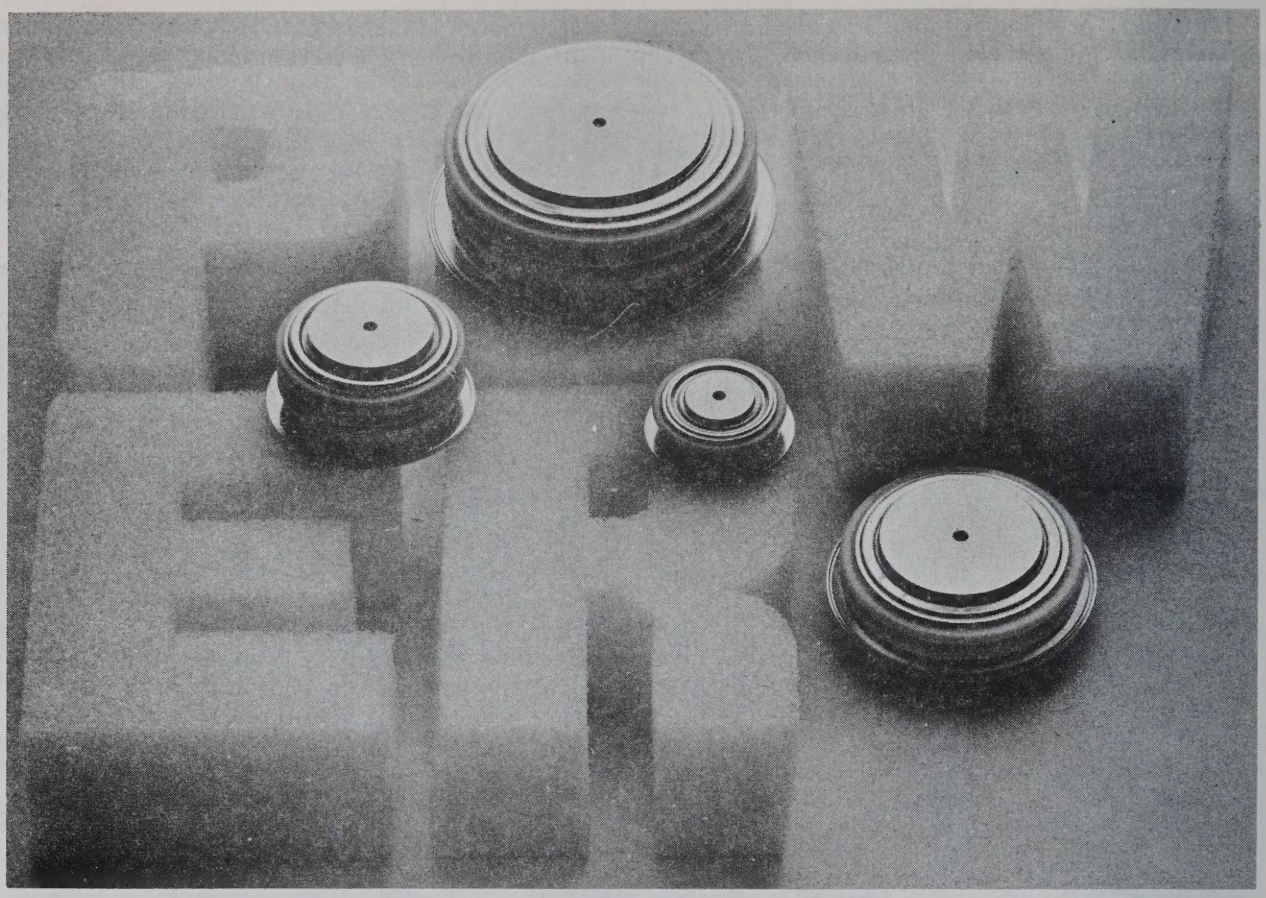

Figure 6.9 Disc packages offer up to 80% improvement in current rating over the same element size in a stud mount package.

between the element and the package. The metallic bond is replaced by a constant-pressure spring washer system (Figure 6.10) which supplies a constant load force to the element. Today, this technique is used to manufacture thermal fatigue free SCR's, rectifiers, and transistors that are magnitudes better than hard solder devices. CBE simplifies the manufacturing process and improves semiconductor reliability. This same design philosophy is employed in the disc package except that the spring clamp system is supplied externally by the user. The Westinghouse worldwide assembly concept owes its success to this patented CBE product breakthrough.

3. KEY MANUFACTURING INNOVATIONS

At the Westinghouse Semiconductor plant, innovative manufacturing procedures are the cornerstone of a large scale manufacturing concept, wherein power semiconductor elements, the heart of the semiconductor device, are the common denominator among worldwide manufacturing plants. This concept is being used to serve the power semiconductor user by guaranteed element availability from an element bank, independent of package requirements. By making package commitment at the last moment, faster delivery, at the required ratings, is made, and an inventory reduction on the part of the user can be realized. Applications, today, require a wide variety of electrical needs. In addition, regional demands require these ratings in an even wider range of

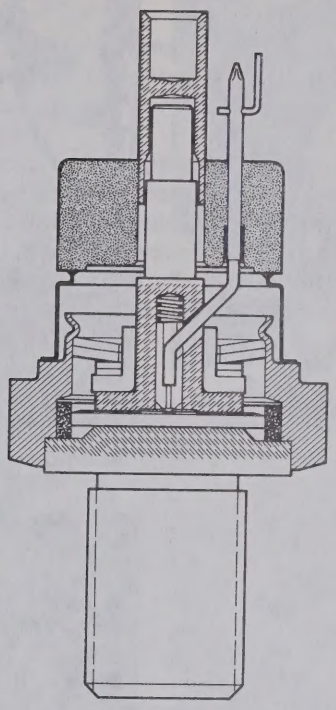

Figure 6.10 Compression Bonded Encapsulation (CBE)

packages or assemblies. This function is well served by the Westinghouse element-oriented manufacturing system wherein the optimum application charcteristics are ensured in processing, test, and package assembly.

Several basic techniques (Figure 6.11) support this element manufacturing system. The spreading resistance probe, developed to predict a product's characteristics instantly, weeks before the product is completed, means better visibility of design characteristics early in the manufacturing cycle. A Westinghouse 2500 process control computer plays an important role in the diffusion cycle by monitoring furnace temperature cycles and cool-down rate to indicate when a deviation from profile occurs. Through the effective use of the computer, the various process cycles are more controllable and predictable, providing a distribution and yield of products to match requirements. A high volume paced conveyor element test line is used to fully characterize an element before committing it to a device package. All standard and special hot or cold tests can be performed on various size elements simultaneously on this test line. After testing, these passivated elements are quality checked and bubble-packed for storage in the World Element Bank until needed. Fundamental to the element system is Compression Bonded Encapsulation (CBE)—a pressure-mounted contacting means for assembling semiconductor elements into a variety of packages—stud, disc, integral heat sink, or flat base. CBE ensures reliability and flexibility in assembly while eliminating thermal fatigue problems inherent in conventional solder construction designs. Accurate and sophisticated testing have made Westinghouse high power semiconductors among the most reliable to be found anywhere. All this adds up to the advantages of predictable, reproducible element characteristics, World Bank stocking, guaranteed emergency delivery, and reduced inventory and cash flow for users of Westinghouse power semiconductors.

4. TECHNOLOGY LEADERSHIP

Indicative of Westinghouse's leadership role in manufacturing high power semiconductors, UNITRA of Poland selected Westinghouse from among suppliers worldwide to provide them with semiconductor technology, facilities, and training. This agreement, for Westinghouse the largest sale of technology ever, was the first of its type by a U.S. manufacturer.

The Semiconductor Division also enjoys the support of the Westinghouse Research and Development Center (Figure 6.12) located in Churchill, Pennsylvania, only twenty-five miles from Youngwood. Thus, a continuous program to provide long range product development and the latest technology and manufacturing techniques is carried on from year to year. Westinghouse invests millions of dollars each year to provide the user with products which offer more efficient energy utilization, promote a cleaner environment, result in greater reliability, reduce size and weight, provide for increased safety, and offer new and expanded capabilities at the lowest possible cost.

A powerful part of your life.

User's Manual
SEMICONDUCTOR GLOSSARY

AQL—Acceptance Quality Level.
Ambient Temperature—Medium or free air temperature in which device is being operated.
Anode—One of two high current terminals of rectifier or SCR; other terminal is cathode.
Assemblies—Combination of discrete devices on heat sinks connected in various circuit configurations.
Average Current—Current integrated over a full cycle. Current measured on DC ammeter.
Base—Control terminal of a transistor.
Beta—See gain.
Blocking Voltage—Ability of a semiconductor to withstand a specific voltage stress without conducting current.
Breakdown Voltage—Maximum voltage a semiconductor can support in its nonconducting direction.
Bridge—Combination of discrete devices on heat sinks; generally in circuit configurations to change A.C. current to D.C. current.
CBE—Encapsulation technique which replaces conventional solder, metallic bonds with a constant-pressure, spring, washer system. This technique eliminates thermal fatigue due to solder joints.
CFM—Cubic feet per minute - amount of air being moved (CFM = LFM x cross-sectional area of heat sink).
Case Temperature—Temperature of package measured at a specific location. Indirect method for determining junction temperature. For stud devices, proper thermocouple location is center of any hex flat — for disc devices, mount thermocouple on rim (radial edge) of pole face.
Cathode—One of two high current terminals of rectifier or SCR; other terminal is anode. In electronic symbol for rectifier or SCR, arrow points toward cathode.
Chip—Small semiconductor element, usually for one to forty amp discrete device ratings.
Collector—One of high current terminals of a transistor; other terminal is emitter.
Commutation—Transfer of current flow from one circuit element to another.
Conduction Angle—Number of electrical degrees that current flows. A full cycle of A.C. voltage or current is 360 electrical degrees.
Creepage Distance—Shortest distance across surface of an insulator between positive and negative terminals.
Dice—See chip.
Diode—See rectifier.
Disc—Semiconductor package that can be cooled from both sides. Various industry names include Pow-R-Disc, Press Pak, Hockey Puck, etc.
Duty Cycle—Ratio of operating time to total operating plus nonoperating time.
Element—Silicon wafer that has been processed to create a semiconductor junction(s), passivated, tested and ready for assembly into a device package.
Emitter—One of high current terminals of a transistor; other terminal is collector.
Encapsulation—Refers to process of assembling a semiconductor element into device package.
End User—Refers to individuals and/or companies who purchase, use, and maintain equipment utilizing power semiconductors.
Failure—Termination of ability of a device to perform its required function. Also see failure mode.
Failure Mode—Refers to type of failure rather than to cause of failure. Component failures are generally either catastrophic (sudden and complete) failures or degradation (parameter drift) failures. Short- and open-circuit failures are catastrophic and usually occur at random. Degradation failures result in deviations from acceptable limits without complete cessation of the function required.
Fast Recovery Rectifier—Term used to describe rectifiers characterized for fast operating response. This class of devices is used for free wheeling diodes and a variety of high frequency applications.
Fast Switching SCRs—Term used to describe SCRs characterized for turn-off time capability and other speed characteristics. This class of devices is used in choppers, inverters, and other high frequency applications.
Flag Lead—Term used to describe top terminal on some stud mount devices. Terminal is a rigid, metal, flag-shaped connection.
Flat Base—Commonly used to describe a studless (clamp down) or a square base (bolt down) device package.
Flex Lead—Term used to describe top terminal on some stud mount devices. Terminal is made from flexible stranded cable.
Forward Direction—The direction of current flow in a semiconductor.
Forward Polarity—See standard polarity rectifier.
Free Wheeling Rectifier (Diode)—Rectifier that is used to bypass the current due to the stored energy in the inductance.
Full Control—Circuit utilizing all SCR's for controlling both half-cycles in an A.C. circuit.
Fusion—See element.
GPM—Gallons per minute. Water flow rate through liquid cooled heat sink.
Gain—The ratio of output to input. Normally used to characterize amplification properties of a transistor.
Gate—Control terminal of an SCR.
General Purpose Rectifier—Term used to describe rectifiers for conventional power control applications where operating speed is not a prime consideration.
Half Control—An arrangement of rectifiers and SCRs that controls only half the cycle in A.C. circuits.
Hard Solder—A high temperature solder having an expansion coefficient very compatible to the element and package base material.
High Voltage Stack—An assembly of a number of semiconductors connected in series to obtain extra high voltage ratings.
Hi-Rel—Abbreviated version of high reliability. Denotes a device having an established level of reliability above that of standard production line product.

Hockey Puck—See disc.

Integral Heat Sink—Refers to a device package which incorporates its own heat sink. Package is very efficient as the element is mounted directly to the heat sink - eliminating the case to sink thermal resistance.

JAN—Refers to device specifications for military use, with Joint Army and Navy sponsorship.

JEDEC—Joint Electronic Device Engineering Council. Sets parameters and specifications for a standard line of devices throughout the industry.

Junction—A transition region between the positive and negative layers of a semiconductor.

LFM—Linear feet per minute. Rate of air flow moving across a cooling surface.

LTPD—Lot Tolerance Percent Defective.

Leakage Current—The small currents which get through or around the blocking characteristic of a semiconductor device, capacitor, or insulator.

MRO—Term stands for Maintenance, Repair, and Operations of a factory, plant, hospital, etc., and refers to the industrial replacement and retrofit market.

MTBF—Mean Time Between Failures.

OEM—Original Equipment Manufacturers who build and sell equipment utilizing power semiconductors.

OSHA—Occupational Safety and Health Administration. Establish and enforce national standards of safety and health in industry.

Parameter—A value, condition, or characteristic that is a measurable property of a device. It may be electrical, mechanical, or thermal and can be expressed for a given set of operational and environmental conditions.

Passivation—A process by which a semiconductor junction is protected against oxidation and contamination.

Pellet—See element.

Phase Control SCR's—Term used to describe SCRs where fast turn-off time is not a prime requirement.

Pole Face—Mounting surface on a disc device; each disc has two pole faces.

Pow-R-Disc—See disc.

Press-Pak—See disc.

Procurement—Overall process of obtaining a semiconductor. Period between selection of required device and receipt of that device.

Pulse—A flow of electrical energy of short duration which is deliberately generated.

RBDT—Reverse Blocking Diode Thyristor. Two-terminal thyristor, ideal for pulse applications because of its high di/dt and fast switching capabilities.

RMS—Abbreviation stands for root-mean-square and refers to the effective heating value of current.

Rating—The ultimate or limiting condition stated for a given device parameter (either maximum or minimum) beyond which the device will not operate properly and/or is not guaranteed by the manufacturer.

Rectifier—A two-terminal device where current can flow in only one direction — from anode to cathode. Low current rectifiers are frequently called diodes.

Reliability—The probability that a system or device will operate for a given period of time and under given operating conditions.

Reproducibility—The ability to produce a group of semiconductors having the exact characteristics of previously produced groups.

Reverse Direction—Describes the direction in which a semiconductor is nonconducting.

Reverse Polarity Rectifier—Denotes the direction of current flow where stud mount base is the anode and the top terminal is the cathode.

SCR—Silicon Controlled Rectifier—Principal member of the thyristor family — is basically a rectifier with a control feature added. This three-terminal device (anode, cathode, and gate) is a controllable on-off switch.

Soft Solder—Any solder that is not "hard solder". Usually has a melting point of approximately 230°C, as compared to the melting point of hard solder which is in excess of 400°C.

Solid State—An electrical device or circuit using semiconductor devices. (Uses no tubes and has no moving parts.) Mechanical relays, switches, rotaries, m-g sets, thyratrons, ignitrons, and vacuum tubes are replaced by semiconductors.

Spike—An unintended flow of electrical energy of short duration. Graphically displayed on a scope as a very high voltage or current having a very short duration — usually in the microsecond range.

Standard Polarity Rectifier—Denotes direction of current flow where stud mount base is the cathode and the top terminal is the anode.

Strike Distance—The shortest distance in air between points of opposite potential. It is the distance through which arcing might occur.

Stud Top—Term used to describe top terminal on some stud mount devices. Terminal is a threaded stud.

Supplier—Power semiconductor manufacturer or authorized distributor.

Thermal Fatigue—The mechanical stress placed on semiconductor interfaces due to the different expansion rates of the various metals being joined.

Thermal Impedance (Resistance)—The resistance to heat flow through a material or from one material to another. The unit is °C/W, which means the centigrade degrees of temperature rise of the material per each watt of power dissipated at the source.

Thermal Shock—Mechanical stresses placed on material or, more expressly, where two different materials are joined together, due to a sudden large change in temperature. Can be destructive.

Thyristor—One of three primary groups of solid state power devices — rectifiers, transistors, and thyristors. Principal members of the thyristor family includes SCR, triac, RBDT, GATT, GCS, GTO, etc.

Transient (Surge) Suppressor—An electrical device used to absorb the energy of extraneous high peaks of voltage or current. Used to protect semiconductors from ruinous overloads.

Transient Voltages—Extraneous spikes of high voltage which appear across a device due to switching, commutating, interruptions, etc. in associated circuitry or by natural forces such as lightning. Transients are of very short duration, usually in the microsecond range.

Transistor—Three-terminal (base, collector, emitter) device used primarily for switching and amplification applications.

User—Refers to both the original equipment manufacturer (OEM) who manufactures equipment utilizing power semiconductors and the end user who purchases, uses, and maintains this equipment.

Vendor—See supplier.

Wafer—A very thin disc of silicon that has been cut from a silicon rod.

How To Use This Book

DEVICE TYPE NUMBER SEARCH

- **If only a JEDEC or Industry Type Number is known:**
  Go to the Master Cross Reference Type Number Index (GENERAL section - Page G3). Using this index, the reader can rapidly locate any power semiconductor JEDEC or industry type number for which Westinghouse offers an exact or suggested replacement along with the page number of the referenced technical data.

or

- **If both the Product Family and the JEDEC or Ⓦ Type Number are known:**
  Go to the Type Number Index at the beginning of the appropriate PRODUCT section. Using this index, the reader can turn directly to the page location for any JEDEC or Ⓦ type number that is listed.

GENERAL APPLICATION SEARCH

- **If a Specific Product Application Requirement is known:**
  Go to the appropriate PRODUCT section and scan the Product Capability Graphs and Product Selector Guides under the appropriate product subgroup. These graphs and guides are presented in order of increasing current rating so the reader can quickly locate a suitable Westinghouse product type along with the page number of the referenced technical data.

or

- **If both a Specific Product Application Requirement and the Desired Device Package are known:**
  Go to the Table of Contents (GENERAL section - Page G2) for the location of the appropriate PRODUCT section, product subgroup, and device package type. The page number reference marks the beginning of the desired data section; the data for a given device package type is presented in order of increasing current rating to simplify the reader's search.

The Ⓦ Power Semiconductor Data Book supersedes all loose-leaf technical data issued prior to January 2, 1978. This technical data is applicable for all Ⓦ power semiconductors manufactured in Youngwood, Pennsylvania.

The semiconductor devices and arrangements disclosed herein may be covered by patents of Westinghouse Electric Corporation or others. Neither the disclosure of any information herein nor the sale of semiconductor devices by Westinghouse Electric Corporation conveys any license under patent claims covering combinations of semiconductor devices with other devices or elements. In the absence of an express, written agreement to the contrary, Westinghouse Electric Corporation assumes no liability for patent infringement arising out of any use of the semiconductor devices with other devices or elements by any purchaser of semiconductor devices or others.

POWER SEMICONDUCTOR DATA BOOK
Assemblies, Rectifiers, Thyristors, and Transistors

TABLE OF CONTENTS

GENERAL

- Master Cross Reference Type Number Index — G3
  - — JEDEC 1N, 2N, 3N Part Numbers — G4
  - — Alpha Industry Part Numbers — G6
  - — Numeric Industry Part Numbers — G22
- Westinghouse Selling Policy/Warranty — G39
- Delivery Lead Time Guidelines — G41
- Military and High Reliability Products — G42
- Application Data
  - — Mounting Power Semiconductors — G43
  - — SCR Gate Turn-On Characteristics — G51
  - — Thyristor Surge Suppression Ratings — G55
- Westinghouse Quick Service Directory — G61

ASSEMBLIES *Introduction, Product Family Index, Selector Guide* — A1

- Modular Rectifier Bridges — A3
- Gold Line, Stud Mount Devices — A5
- Air and Liquid Cooled Disc — A37
- Manifold AC Switch, Liquid Cooled — A52
- Kits and Sinks — A65
- High Voltage Rectifier Stacks — A69

RECTIFIER *Introduction, Type Number Index, Selector Guides* — R1

- General Purpose
  - — Axial Lead Mount — R9
  - — Stud Mount — R13
  - — Disc Mount — R39
- Fast Recovery
  - — Stud Mount — R55
  - — Disc Mount — R67

THYRISTOR *Introduction, Type Number Index, Selector Guides* — S1

- Phase Control SCR's
  - — Stud Mount — S9
  - — Disc Mount — S41
  - — Integral Heat Sink — S71
  - — Flat Base — S73
- Fast Switching SCR's
  - — Stud Mount — S77
  - — Disc Mount — S83
- Reverse Blocking Diode Thyristor (RBDT)
  - — Stud Mount — S95
  - — Disc Mount — S97

TRANSISTOR *Introduction, Type Number Index, Selector Guides* — T1

- NPN Power
  - — General Purpose (TO-66/TO-3) — T5
  - — High S.O.A. (Stud Mount) — T15
  - — High Power Fast Switching (Stud and Disc Mount) — T33

MANUFACTURER'S CODES

ATS—Atlantic Semiconductor/Diodes, Inc.
DEL—Delco Electronics
EDI—Electronic Devices, Inc.
EDL—Edal Industries
GE—General Electric
GI—General Instrument
IR—International Rectifier

SYN—Syntron (FMC)
TUN—Tungsol
UNI—Unitrode
VAR—Varo
WCE—Westcode
WES—Westinghouse Electric

The Ⓦ replacements represent what we believe to be equivalents for the products listed. Emphasis has been placed on providing the user with a replacement device of the same current and voltage rating when possible. The user must determine the substitution acceptability by reviewing the electrical, mechanical, and thermal characteristics presented in the referenced technical data sheets. Westinghouse assumes no responsibility for guaranteeing the acceptability of any suggested replacement in this master cross reference type number index.

PRODUCT TYPE NOTES

A—Assembly
D—Drawing (Consult Factory)
R—Rectifier
S—SCR
T—Transistor

REPLACEMENT NOTES

CF—Consult Factory
SO—Special Order—limited availability
XX(5th & 6th digits of Ⓦ Product Description Number)—Replace with appropriate two-digit numeric voltage code.

Note: Manufacturer's Codes, Product Type Notes and Ⓦ Replacement Notes are listed on page G3

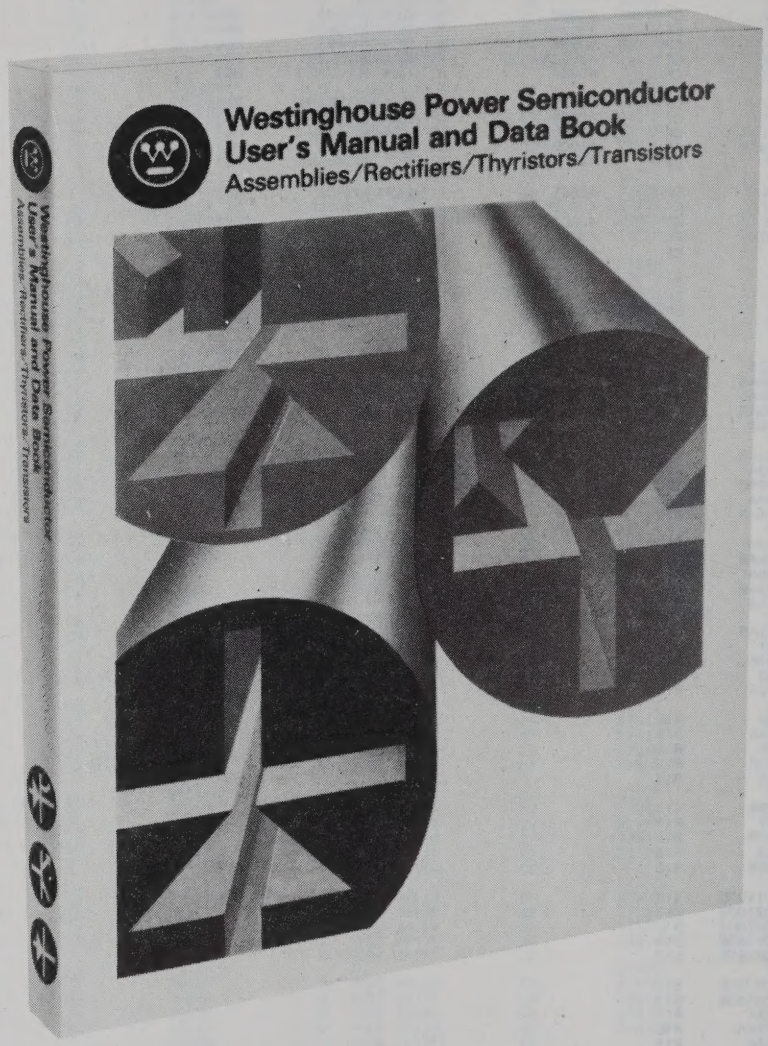
Designed with YOU in Mind

Ideal for all users of power semiconductors regardless of job function, technical background, and experience level.



- Two books in one
- 8½ x 11 format
- Easy to read
- Fully indexed
- Master cross reference
- Complete product data
- 432 Pages

U.S. $6.50 • Book Rate Postage Included • Elsewhere $7.50

This valuable reference book will save you time and money when specifying, buying, installing, testing, maintaining, trouble-shooting, servicing, identifying, and replacing power semiconductors. Order your copy today.

Send check or money order (payable in U.S. funds) to:

Acceptance of Orders

The conditions stated below shall take precedence over any conditions which may appear on your standard form, and no provisions or conditions of such form, except as expressly stated herein shall be binding on Westinghouse. Notice of objection to any additional or different terms is hereby given.©

Order Entry

Send all orders for quantities shown in PL 54-020 to our authorized full line Westinghouse distributor. Orders for larger quantities may go to:

Westinghouse Electric Corporation
Semiconductor Division
Youngwood, Pennsylvania 15697
Telephone: 412-925-7272
TWX: 510-468-2840

Standard Conditions of Sale

Price Policy

Prices are firm for orders specifying delivery within six months from acceptance of order by Westinghouse. Shipments scheduled beyond six months from order acceptance, or held or postponed beyond such six months at the request of buyer, are subject to price adjustment to price in effect at time of shipment. Such adjustment will not apply to products scheduled for shipment within thirty days of the date of notification to buyer of the price adjustment.

Minimum Billing

The minimum order shall be **$250.00** plus transportation charges.

Taxes

The prices do not include any Federal, State or Local property, license, privilege, sales, use, excise, gross receipts or other like taxes which may now or hereafter be applicable to, measured by or imposed upon or with respect to the transaction, the property, its sale, its value or its use, or any services performed in connection therewith. Purchaser agrees to pay or reimburse any such taxes which Westinghouse or Westinghouse's subcontractors or suppliers are required to pay.

Terms of Payment

Terms of payment are net within 30 days from date of shipment.

Payments

If, in the judgment of Westinghouse, the financial condition of the purchaser, at any time during the manufacturing period, or at any time product is ready for shipment, does not justify the terms of payment specified, Westinghouse may require full or partial payment in advance.

Delivery

F.O.B.-P.S.-Frt./Coll. (Transportation charges, not allowed). This product is delivered Free on Board, Point of Shipment, Freight Collect (Transportation Charges not allowed).

Loss, Damage, or Delay

Westinghouse shall not be liable for failure to perform or for delay in performance due to fire, flood, strike or other labor difficulty, act of any governmental authority or of the purchaser, riot, embargo, car shortage, wrecks or delay in transportation, inability to obtain necessary labor, materials, or manufacturing facilities from usual sources or due to any other cause beyond its reasonable control.

In the event of delay in performance due to any such cause, the date of delivery or time for completion will be postponed by such length of time as may be reasonably necessary to compensate for the delay.

Warranty

Lifetime Guarantee

Westinghouse warrants to the original purchaser that it will correct any defects in workmanship or material, by repair or replacement, F.O.B. factory or, at its option, issue credit at the original purchase price, for any silicon power semiconductor bearing this symbol ✚ during the life of the equipment in which it is originally installed, provided said device is used within manufacturer's published ratings and applied in accordance with good engineering practice.

Other Semiconductor Products

Westinghouse, in connection with products sold, agrees to correct any defect or defects in workmanship or material which may develop under proper or normal use during the period of one year from the date of shipment, by repair or replacement f.o.b. factory, of the defective part or parts, or, at its option, issue credit at the original purchase price.

Developmental Products

Westinghouse semiconductor products designated at the time of sale to be developmental are warranted to meet the applicable preliminary specifications in effect at time of order entry. If any failure to comply with such preliminary specifications appears within 12 months from date of shipment, Westinghouse will correct such non-compliance by repair or replacement f.o.b. factory, or, at its option, issue credit at the original purchase price.

The foregoing warranties are exclusive and in lieu of all other warranties of quality whether written, oral, or implied (including any warranty of merchantability or fitness for purpose).

Correction of non-conformities in the manner and for the periods of time specified above shall constitute fulfillment of all liabilities of Westinghouse to the purchaser whether based on contract, negligence or otherwise in respect to such products.

Limitation of Liability

Neither party shall be liable for special, indirect, incidental or consequential damages. The remedies of the purchaser set forth herein are exclusive and the liability of Westinghouse with respect to any contract or sale or anything done in connection therewith, whether in contract, or in tort (including negligence) shall not exceed the price of the equipment or part on which such liability is based.

Patents

Westinghouse shall at its own expense, defend any suits or proceedings brought against the purchaser, and/or its vendees, mediate and immediate, so far as based on an allegation that any goods, material, equipment, device or article (hereinafter referred to as product) or any part thereof furnished hereunder constitutes an infringement of any claim of any patent of the United States, other than a claim covering a process performed by said product or another product produced by said product, provided that such product is not supplied according to purchaser's design, and is used as sold by Westinghouse, if purchaser

Supersedes Selling Policy 54-000, pages 1 and 2,
Dated February 26, 1976

Patents, Continued
shall have made all payments then due hereunder, and if Westinghouse is notified promptly in writing and given authority, information and assistance for the defense of said suit or proceeding, and Westinghouse shall pay all damages and costs awarded in any suit or proceeding so defended, provided that this indemnity shall not extend to any infringement based upon the combination of said product or any part or parts thereof with another product or things not furnished hereunder unless Westinghouse is a contributory infringer. Westinghouse shall not be responsible for any settlement of such suit or proceeding made without its written consent. In case the product or any part thereof furnished hereunder is in any suit or proceeding so defended held to constitute infringement, and its use is enjoined, Westinghouse shall, at its own option and its own expense, either procure for the purchaser the right to continue using said product or part thereof; or replace it with a non-infringing product; or modify it so it becomes non-infringing; or remove it and refund the purchase price and the transportation and installation costs thereof. The foregoing states the entire liability of Westinghouse with respect of patent infringement by said product or any part thereof.

To the extent that said product, or any part thereof, is supplied according to purchaser's design or instructions, or is modified by purchaser, or combined by purchaser with another product or things not furnished hereunder except to the extent that Westinghouse is a contributory infringer, or is used by purchaser to perform a process, or produce another product, and by reason of said design, instruction, modification, combination, performance, or production, a suit or proceeding is brought against Westinghouse, purchaser agrees to indemnify Westinghouse in the manner and to the extent Westinghouse indemnifies purchaser in the preceding paragraph insofar as the terms thereof are appropriate.

Title – Risk of Loss
The product shall remain the personal property of Westinghouse until fully paid for in cash, and the purchaser agrees to perform all acts which may be necessary to perfect and assure the retention of title to such property by Westinghouse. Risk of loss of the product, or any part of the same, shall pass to the purchaser upon delivery of such product or part, F.O.B., point of shipment.

© Changed since previous issue.

The purchaser should immediately inspect each shipment, and if there is evidence of loss or damage during transit, should file a claim against the carrier. Westinghouse may assist with such claims, but will not accept any responsibility for the claims. Any adjustments in such cases are between the purchaser and the carrier.

License Notice
The sale of any product hereunder does not convey any license, express or implied, under any patent claims on circuits, systems or processes, or on any combination of the product with other devices, elements or things.

Termination©
Any order may be terminated by the purchaser only upon payment of reasonable cancellation charges which will be determined by Westinghouse in conjunction with expenses and commitments incurred.

The minimum charge for an order which is cancelled after Engineering has been completed prior to release to Production will be $250.00, or 2% of the selling price, whichever is greater. If an order is cancelled after it has been released to Production, an additional charge will be made in proportion to the percentage of completion of the order. The additional charge will be based on material, labor, and overhead costs plus a 15% markup to compensate for disruption in scheduling, disruption in planned production, lost profit, and other indirect costs.

Returning Product
Authorization and shipping instructions for the return of any product must be obtained by the purchaser from Westinghouse before returning the product. Product must be returned with complete identification in accordance with Westinghouse instructions or it will not be accepted. Where a purchaser requests authorization to return product for reasons of his own, he will be charged for placing the returned goods in salable condition (restocking charge) and for any outgoing and incoming transportation paid by Westinghouse.

In no event will Westinghouse be responsible for product returned without proper authorization and identification.

DELIVERY LEAD TIME GUIDELINES

This schedule is to be used for general planning guidelines only. These typical factory lead times listed do not include order transmittal time to the semiconductor factory or shipping time to the user's plant. Please contact Westinghouse for specific requirements. Check with the local authorized distributor for off-the-shelf delivery on most rectifier, SCR, transistor, and modular rectifier assembly products.

There are several points worth noting about power semiconductors when planning for volume purchases. Semiconductors are yield dependent devices — once manufactured, if they don't meet the desired specification, they usually cannot be altered or modified. Also, ordering the highest current rating, highest voltage rating, and fastest turn-off time device in a given product family usually results in a longer lead time due to lower production yield. As with most any type of manufactured product, unforeseen delays in shipping product due to late parts delivery, parts shortages, receipt of inferior or out-of-spec component parts, can occur. The actual quantity required by the user of a given semiconductor type as well as the general market demand for the device can also affect the product's lead time. Therefore, the user should work closely with the manufacturer to assure on-time delivery of the needed semiconductors.

The best way to assure a steady flow of semiconductors into your plant is to enter a purchase order on the manufacturer with scheduled monthly releases. An alternate approach would be a purchase agreement to buy a certain number of power semiconductors (particular type) in a specified period of time. The purpose of either of these approaches is to provide the semiconductor manufacturer with better planning visibility so that the factory can match its production schedule to your actual requirements.

*Gain Rated Current

For volume users of high power semiconductors, Westinghouse offers a program that can help save you and your company time and money. Westinghouse will carry your safety stock, at no cost to you, in the form of a bonded element inventory selected to your specifications and with guaranteed delivery time for encapsulating these elements into any device package you desire. In addition, this program will allow Westinghouse to respond more rapidly to sudden increases in your production levels. Therefore, by letting Westinghouse carry your safety stock, you not only get a guaranteed delivery lead time, but your company realizes an improvement in its cash flow as a result of the reduction in committed captial. For fast delivery and prompt service, specify Westinghouse power semiconductors.

MILITARY and HIGH RELIABILITY PRODUCTS

Westinghouse has been a pioneer in the manufacture of reliable power semiconductors for both commercial and military applications worldwide. From simple conditioning tests to a full-scale high reliability test program, Westinghouse can deliver a product to meet any required level of reliability.

A complete line of high power military rectifiers are available in both standard and reverse polarity. The JAN type numbers and their respective ratings are as follows:

VOLTAGE RATING	100 Ampere/DO-8 Package MIL-S-19500/246 TYPE NUMBER	240 Ampere/DO-9 Package MIL-S-19500/211 TYPE NUMBER
200V	JAN 1N3289, R	JAN 1N3164, R
400V	JAN 1N3291, R	JAN 1N3168, R
600V	JAN 1N3293, R	JAN 1N3170, R
800V	JAN 1N3294, R	JAN 1N3172, R
1,000V	JAN 1N3295, R	JAN 1N3174, R

For copies of the military specifications, contact the Commanding Officer, Naval Publications and Forms Center, 5801 Tabor Avenue, Philadelphia, Pa. 15120.

Westinghouse power semiconductors have been selected for use in a variety of high reliability programs.

For the utmost in reliability, specify Westinghouse power semiconductors.

Application Data
MOUNTING POWER SEMICONDUCTORS
Assemblies, Rectifiers, Thyristors, and Transistors

Introduction

Semiconductor devices control large amounts of power with high efficiency and reliability. With ever-increasing circuit and device power levels, the requirement for adequate cooling of semiconductors is mandatory. The problem for the user is to properly assemble the devices into equipment without reducing thei: capability. Regardless of whether the device is a lead mount, stud type, flat base or disc, certain mounting procedures must be adhered to in order to get the most reliable device operation. The amount of heat involved requires proper mounting to prevent unwanted temperature rise or damage to the semiconductor. This AD sheet discusses proper mounting methods and surface preparation required for successfully applying semiconductors.

Thermal Resistance Analogs

Semiconductor heat flow is conveniently depicted by the thermal-electrical analog illustrated in Figures 1 and 2. These figures show the heat flow paths for the stud and disc type devices, respectively. The discussion will cover one heat flow path as in Figure 1, but apply equally to Figure 2. In the diagrams, the following quantities are analogs.

Mechanical Parameter		Analog	
T	—Temperature	V	—Voltage
ΔT	—Temperature Difference	ΔV	—Voltage Difference
*R_θ	—Thermal Resistance	R	—Electrical Resistance
P	—Heat Source	I	—Current Source

*R_θ —Units of °C/Watt
P —Units of Watts

Thermal losses at the junction and in device resistance must be conducted through device and package to the ambient. Under stable operating conditions, the resulting ΔT, between the junction and the ambient is expressed as

$$\Delta T_{JA} = P \times R\theta JA$$

For stud and disc types Rθ is made up of three quantities so the thermal equation may be written:

$$\Delta T_{JA} = P(R\theta JC + R\theta CS + R\theta SA)$$

Stud type thermal resistance ($R\theta JC$) is determined by device design. The heat sink thermal resistance, ($R\theta SA$), is similarly fixed by the dissipator selected and the amount of coolant used. The remaining thermal resistance quantity, $R\theta CS$, is the variable which should be reduced to lowest practical levels by proper mounting procedures. These procedures include preparation and treatment of the mating surfaces, use of joint compounds, and applying the required force to the mating surfaces.

When using disc devices the $R\theta JC$ value is effected by how well the recommended mounting force is applied. The case to sink properties for this double side cooled device responds in the same manner described for stud type devices.

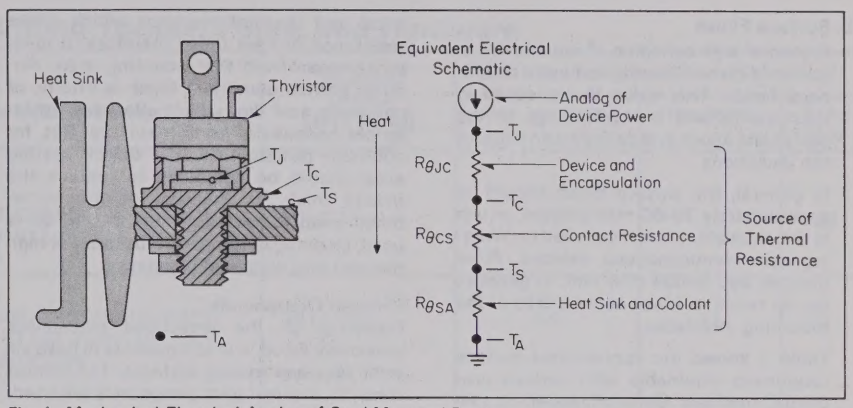

Fig. 1: Mechanical-Electrical Analog of Stud Mounted Device.

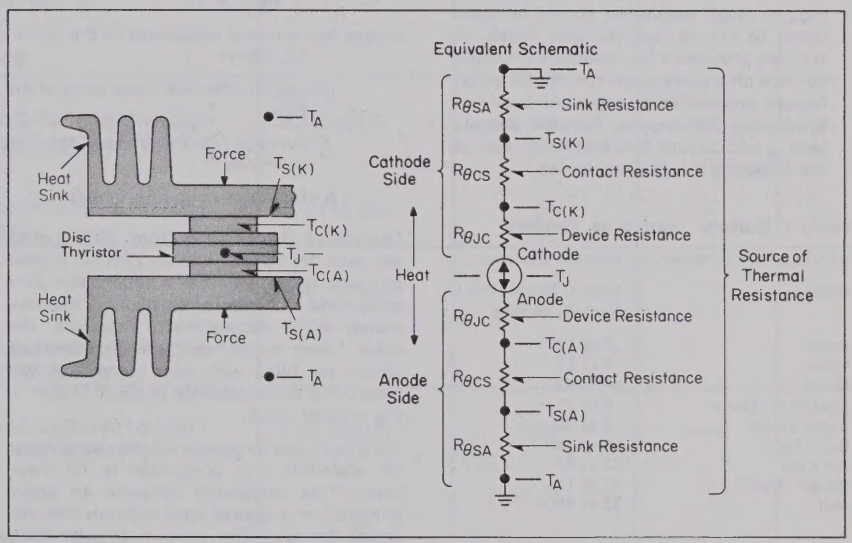

Fig. 2: Mechanical-Electrical Analog of Disc Mounted Device with Double Sided Cooling.

Lead mount semiconductors have their internal resistance predetermined by how well they are soldered together. The axial lead, bonded directly onto the wafer takes heat out of the body and radiates it to the surrounding ambient. A detailed thermal analysis is provided in the lead mount data sheet.

These lead mount devices are not affected by load force, and surface finish as are the higher power devices mentioned previously.

Surface Requirements

The condition of the sink mounting surface is one of the most important mounting details. The following sections describe what limits should be met on flatness and surface finish to minimize mounting resistance due to surface problems.

a. Surface Flatness

Surface flatness is specified as a total indicator reading (TIR), measuring the maximum distance between the crests and valleys of the mounting surface. The flatness of the mounting plane is referenced to the maximum deviation measured in the device mounting area.

For satisfactory mounting, the device seating area should be held from .0005 to .001 TIR. Commercial extruded heat sinks do not have comparable flatness values. In addition, cast sinks, rough plates, etc. will require additional treatment.

b. Surface Finish

A second sink condition of importance is surface finish. All surfaces have a roughness factor. This value is expressed in microinches and is the average of the deviations above and below mean value of the deviations.

In general, the surface finish should be approximately 30-60 microinches, which is the equivalent finish supplied on Westinghouse semiconductor devices. Finer finishes add undue cost and, in general, do not result in lower contact drop at the mounting interfaces.

Table 1 shows the approximate surface roughness obtainable with various production methods. Generally speaking, mill finish or machined surfaces on copper or aluminum will be satisfactory if they are flat and free from deep scratches. Castings or rough extrusions should be spotfaced to insure flatness and finish. A suitable procedure is to measure a sample surface on a production run, and if satisfactory, proceed with production based on machining techniques. Periodic sample testing will assure that tool wear, etc., is not affecting the desired values.

Table 1 Surface Texture vs. Process

All Values are in Micro-inch Average Deviation

Process	Normal Range (Min.) Average Tooling
Polish	4 to 16
Hone	4 to 32
Grind	4 to 63
Electrolytic Grind	8 to 32
Barrel Finish	8 to 32
Bore, Turn	16 to 250
Die Cast	32 to 63
Broach, Ream	32 to 125
Mill	32 to 250

Treated Mounting Surfaces

To produce a reliably low electrical and thermal resistance between the contacting surfaces it is necessary that they be free of all foreign material, oxides, and films. Freshly machined surfaces are generally free of these contaminants if used immediately. Bear in mind that freshly bared aluminum forms an oxide film in a matter of seconds. Other types of metals, such as copper and steel, oxidize more slowly.

As a precautionary measure, all mating surfaces, and particularly aluminum, should be used immediately after machining. If they are stored, a cleaning operation is good practice. A satisfactory cleaning technique is to polish the mounting area with No. 000 fine steel wool, followed by an alcohol or warm soap and water wipe.

Many aluminum heat sinks are black anodized for appearance, durability, and performance; however, anodizing is an electrical and thermal insulator which offers resistance to heat flow. Therefore, it must be removed from the mounting area. Another treated aluminum finish is irridite, or chromate acid dip, which offers low resistances because of its thin surface. But, for optimum performance, the device seating area should be spotfaced to remove the irridite finish. For economy, paint is sometimes used for sinks. When this finish is used, cleaning is mandatory, because of high thermal and electrical resistance.

Thermal Compounds

Following all the prescribed procedures previously listed, it is still possible to have air voids between mating surfaces. To optimize contacts, thermal joint compounds are used.

The formula for thermal resistance of any substance is:

$$R\theta = \rho t/A$$

where $R\theta$ = thermal resistance of the film in °C/Watt

ρ = specific thermal resistance of the film

t = average film thickness of the film in inches

A = film area in square inches

The values of ρ will vary from .10°C inches per watt for copper film to 1200°C inches per watt for air, whereas a satisfactory joint compound will have a resistivity of approximately 60°C inches/watt. Therefore, the voids, deep scratches, and imperfections which are filled with joint compound, will have a thermal resistance of about 1/20th of the original value.

Westinghouse recommends the use of Alcoa #2 electrical joint compound to fill these voids. This compound contains an active chemical in a grease type medium that dissolves the oxide film, present on most heatsink mounting surfaces, and seals the joint against moisture. Some compounds attack the surface, with localized action going relatively deep. With this compound, however, the surface is lightly etched with no deep localized attack; it attacks the oxide and not the metal.

All heat exchanging surfaces should be cleaned as mentioned previously. Apply Alcoa #2 compound to all heat exchanging surfaces sparingly with the use of a spatula or lintless brush. Another method is to place a predetermined minimal amount at or around the center of the contact area and then rotate the device back and forth while pressing it into the heat sink. In this fashion, excess compound will be forced out and may be wiped clean. Prolonged skin contact with the compound should be avoided since it does contain a fluoride base. It is recommended that after using the compound, any skin areas which were in contact with the compound should be washed clean.

Other approved thermal compounds are Dow Corning 342 available from Dow Corning Corporation in Midland, Michigan or Silicone Oil SF 1154 available from the General Electric Company.

Mounting Pressures

Optimum mounting pressures for device types have been determined by empirical tests. Based on the results of these experiments, the device tabulations were generated for Table 2. Lower than recommended torques or forces can result in overheating and higher values may result in cracked silicon or internal contact problems. For higher or lower torque and force values, contact Westinghouse.

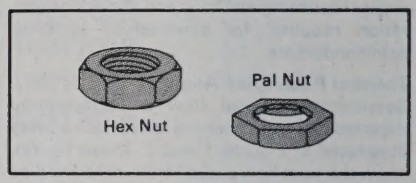

Fig. 3-A: Typical Non-insulating Hardware Kit.

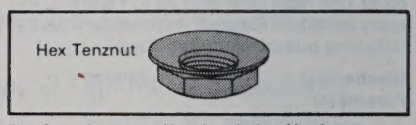

Fig. 3-B: Alternate Non-insulating Hardware.

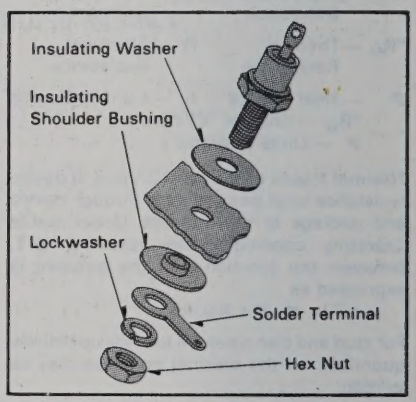

Fig. 3-C: Typical Insulating Hardware Kit Assembly

Standard mounting hardware for stud devices includes a nut and locking washer, or a pal nut. With either combination, the nut should be carefully tightened applying the torque indicated for the type of device shown in Table 2.

An illustration of standard mounting hardware for stud devices is shown in Figure 3. Standard hardware kits are available to accomodate mounting all semiconductor types. The appropriate kit is identified by a code number as shown in the last three columns of Table 2. These codes are explained in Table 3 as to what components come in each kit.

Alcoa #2 Joint Compound is available from ... Alcoa Conducta Products Company, Division of Aluminum Company of America, Pittsburgh, Pennsylvania.

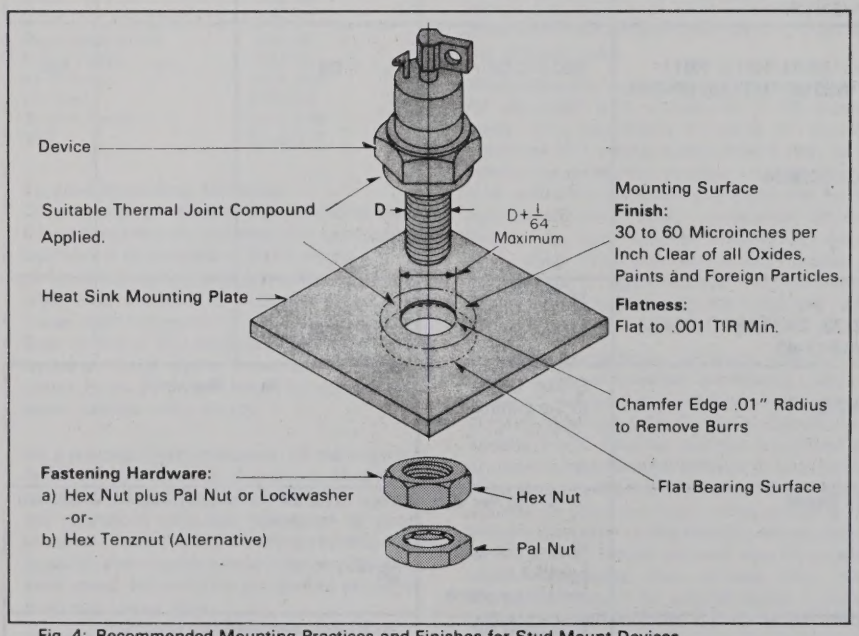

Fig. 4: Recommended Mounting Practices and Finishes for Stud Mount Devices.

Mounting of Stud Type Devices

Figure 4 presents an exploded view of a stud-type device and shows the various recommendations of surface flatness and finish. It should be noted that the diameter of the mounting hole should not exceed the diameter of the stud by more than 1/64" and that the edge of the hole should have a chamfer not exceeding .01" radius.

The fastening hardware shown consists of a nut and a locking feature, either pal nut or lock washer. Either type will work as long as proper torque is applied. It is very important to apply the torque with a good torque wrench such as those sold by P.A. Sturtevant Co. and Snap-On Tools Corporation or other reputable firms.

It should be noted that Westinghouse does not recommend as standard practice drilling and tapping holes for mounting stud type devices. This is due to the need for 1/10 of a degree perpendicularity necessary between the hole and mounting surface.

Mounting Flat-Base Devices

In mounting flat-base devices the required pressure is obtained by fastening the device corners or edges with bolts. The pressure should be applied in a staggered fashion such as tightening opposite corners to one half the

recommended torque as per Table 2 and then finally apply the necessary remaining torque in the same staggered fashion. Special "studless" devices are mounted by mounting springs as shown in Figure 5. Proper mounting pressure is applied when the spring is flat and parallel to the heat sink surface.

Mounting Discs

Disc's achieve higher current ratings due to improved heat transfer capabilities. This is made possible by two heat paths and greater heat conduction area. Since these devices are fabricated without mounting features, such as studs, plates or retainer assemblies, the devices must be mounted with external force.

The required clamping force must be applied perpendicular to the disc surfaces and should be uniformly distributed over the total contact areas. To achieve this, the clamping system must assure sink-device parallelism via appropriate clamp construction and mounting technique.

Westinghouse offers a clamp which provides uniform distribution of the required pressure. This distribution of pressure is accomplished by a ball and socket type gimbaling mechanism. The force is applied via a spring bar or bars depending on the magnitude of the force to be delivered. This clamp is available with a mechanical force gauge to acknowledge what force is applied. The stud length is variable to accomodate different lengths of clamping columns.

An exploded view of an assembly consisting of a disc type semiconductor with double side cooling and the Westinghouse clamp is shown in Figure 6.

A recommended procedure for mounting disc types is as follows:

1. Check mounting surfaces of semiconductor and heat exchanger to insure no large scratches, nicks or irregularities are present.
2. Mounting surfaces should be free of oxides, films or foreign materials in order to have good heat exchanging properties. Surfaces should be rubbed lightly with 000 steel wool and swabbed with alcohol immediately prior to assembly. Surfaces should not be touched after cleaning. Parts may be placed on a lint free surface until final assembly.
3. Pre-assemble any roll locating pins to be used with a light hammer into the center dowel hole in each heat sink if necessary. A gauge block is useful to prevent excessive length of this pin.
4. Polarity of the device should be checked prior to assembly to insure the device is installed in the desired direction.
5. For assembly the contact surfaces of the semiconductor and heat sink should be

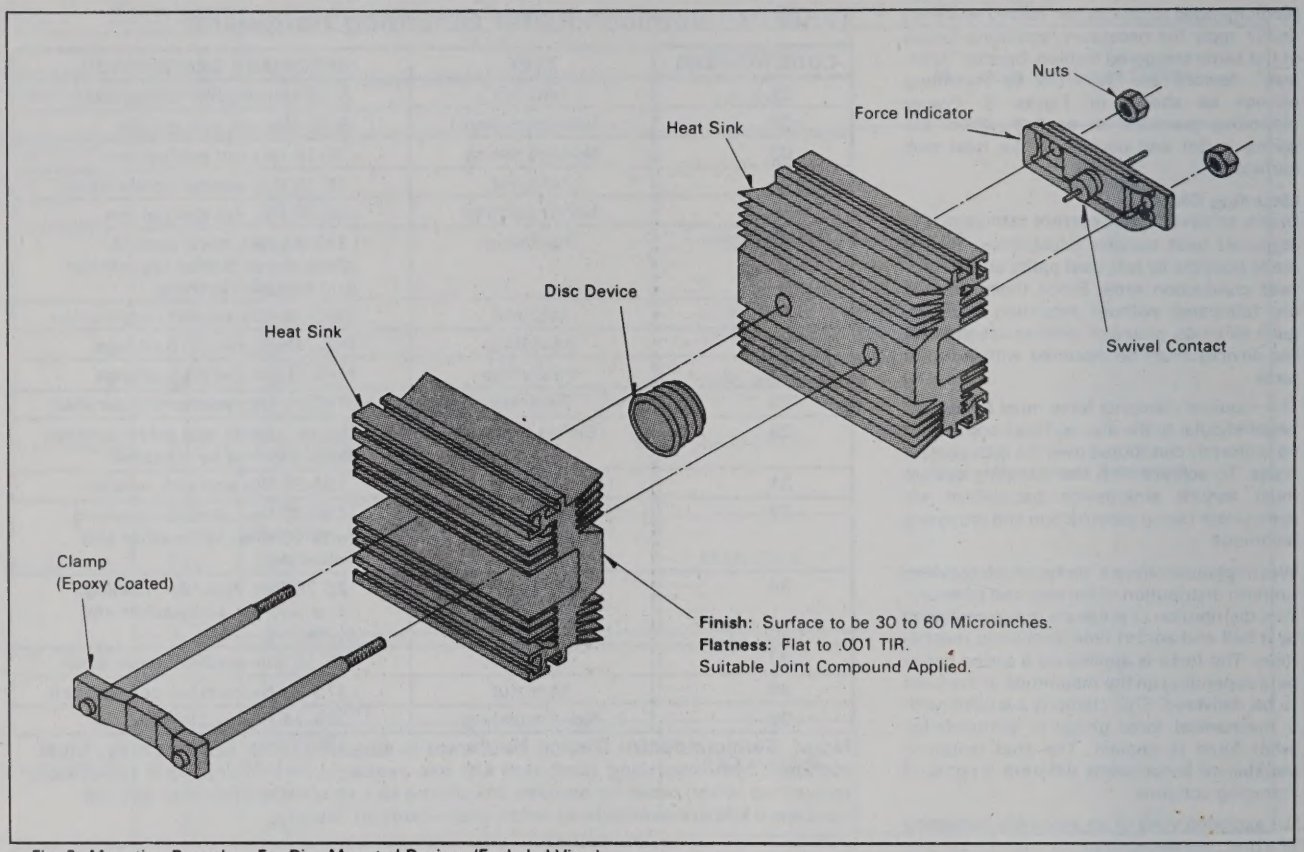

Fig. 6: Mounting Procedure For Disc Mounted Devices (Exploded View).

lightly coated with Alcoa #2 (or suitable substitute). The device should then be centered on the heat sink. If dowel pin locators are used the device should be placed with its locator holes over the projections. The device should then be rotated through 180° to distribute the compound.

6. The appropriate clamp may now be inserted through the heat sink. The clamp force bar with mechanical force gauge must be initially adjusted to give a zero force reading. The spring bar may now be placed over the studs and the centering pin located in the hole provided. The nuts may now be finger tightened, in an even fashion such that approximately the same number of threads show above each nut.
7. To achieve the correct mounting force apply either half or quarter turns per nut in a staggered fashion until the gauge indicates the correct force.

Remounting Disc Devices

In some instances devices must be replaced in the field. The procedure to be used is similar to the mounting procedure just outlined with the following additions:

1. **Removing the Device**
   Disassembly should be made by loosening the clamp nuts in a staggered fashion, i.e., one half turn from one nut, one half turn from the other, etc., until the nuts can be removed by hand.

2. **Re-Zeroing Clamp Gauge**
   Make sure that the gauge is set to zero before using again. This is done simply by bending the indicator until a zero force is indicated.

3. **Cleaning and Coating of Clamp Threads**
   While the clamp is disassembled, clean the threads with a light brushing and then wipe with a cloth. Prior to using the clamp a coating of Anti-Seize or Never-Seez non-galling compound should be applied to the threads.

WARNING:
Due to the high load forces placed on these clamps breakage could occur when torsional force is being applied to the threads resulting in the broken bolt becoming a flying projectile. Safety precautions must be taken to prevent bodily harm.

As indicated earlier, proper device loading is necessary to guarantee good thermal performance. With disc devices power dissipating properties are also affected by loading effectiveness. Figures 7a and 7b illustrate the typical effect of mounting force on thermal performance and device forward voltage drop for discs.

Parallel Mounting of Disc Devices

For applications requiring greater current output than can be obtained from one device, two or more devices can be readily paralleled. It is necessary, however, to take simple precautions to allow for possible variations in height of the devices. A rigid heat sink may be used and will serve as a base for the units to be paralleled, but the other side of the devices should be cooled by individual heat sinks. Individual clamps are required for each device to provide the required pressure.

Stack Mounting of Disc Devices

The flat symmetrical design of the disc package permits stacking the devices to obtain a number of circuit configurations. A single clamping device can be used with the length of bolt adjusted to clamp the total

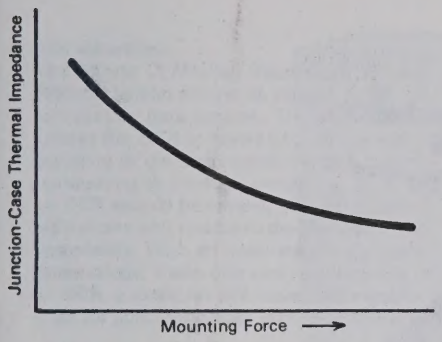

Fig. 7A: Typical Junction-Case Thermal Impedance Variation as a Function of Mounting Force for Disc Type Devices.

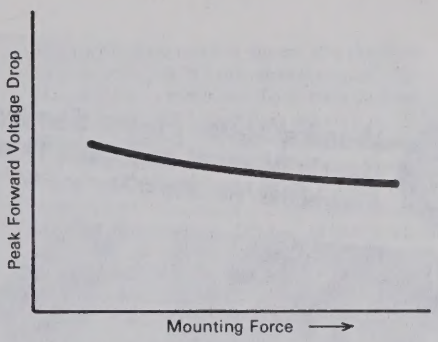

Fig. 7B: Typical Forward Voltage Drop Variation as a Function of Mounting Force For Disc Type Devices.

length of the stack. The limit of stacking, of course, depends on the rigidity of the assembly and the amount of expansion and contraction which can be tolerated during operation. Both problems can be solved by proper fixture design for assembly and by selection of springs with suitable load-deflection characteristics. When stacking devices in one clamped column it is necessary to keep sink mounting surfaces parallel to within .0005 inch if devices are to be mounted on both sides of the sink such as in many plate designs.

Figure 8 shows the basic configurations which may be obtained in a single stack. These include parallel, series, center tap, doubler and three-phase, full wave circuits. Many others are possible. The diagrams use diode circuits for simplicity of illustration. They are applicable to SCR's connected in series and to complete isolated circuits wherein insulated spacers may replace devices in the mechanical assembly.

Heat Sink Considerations

The previous discussion referred indiscriminately in the various sections to either plate-type or to extruded heat sinks. The plate-type is the simplest to use and may be of copper, aluminum or any thermally conductive material. The aluminum extrusions are the most common heat sinks presently used and furnish a greater exposed surface for heat transfer to the ambient atmosphere.

The heat-transfer characteristics of any heat sink, under normal convection conditions, can be greatly enhanced by using either forced air or some liquid coolant. The use of a liquid coolant is considerably more efficient. Liquid cooled sinks are generally cast or machined. Either is highly efficient but cast heat sinks have very little waste in fabrication and have very low pressure drop. The flow of coolant through the sinks is usually controlled to hold the semiconductor temperature to the designed maximum level.

A complete line of air and liquid cooled heat sinks are available to accommodate all disc type semiconductors. In addition, Westinghouse offers a full line of air and liquid cooled assemblies for all power semiconductors.

SCR GATE TURN-ON CHARACTERISTICS
Gate Drive Requirements

Introduction
The Silicon Controlled Rectifier (SCR) is a thyristor which attains its power control function by gate turn-on. The gate signal causes the SCR to revert from a forward blocking or off-state condition to a current conducting or on-state condition. Turning on an SCR should be simple, but circuit considerations and device trade-offs add some complexity. With an understanding of gate terminology, trade-offs and requirements of an SCR, a designer will have better guidelines for specifying gate turn-on requirements.

V/I Characteristics of an SCR
The SCR is a three terminal thyristor, properly defined as a Reverse Blocking Triode Thyristor. The V/I characteristics relationship is shown in Figure 1.

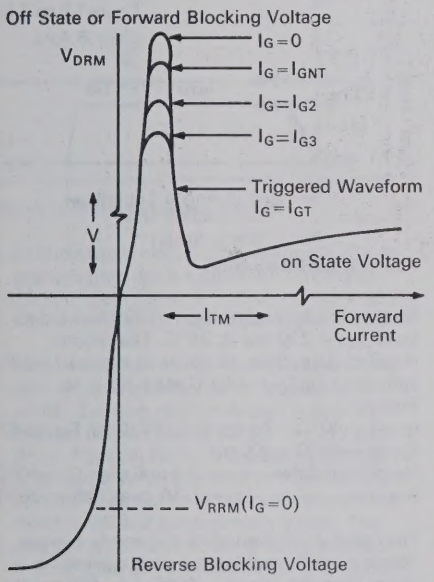

Figure 1. Voltage Current Characteristics Using Gate Control.

Without a gate control signal, the thyristor blocks voltages in both directions, so that power flow is inhibited. To initiate power flow, the SCR is gated only when it is in the forward blocking (V_{DRM}) off state. Increasing the gate signal I_G from 0 to I_{GT} shows that the SCR's ability to block voltage decreases until it turns on. The reverse blocking voltage characteristic (V_{RRM}) is like a rectifier diode. If one were to leave on a gate signal while the SCR becomes reverse biased, it is possible that the SCR would fail due to increased leakage current.

The SCR can be turned on by three methods; viz.,

- The recommended application of a gate current and voltage to the gate cathode potential leads.
- Two-terminal turn-on by exceeding the non-repetitive forward blocking (off-state) voltage rating, referred to at times as V_{BO} turn-on.
- dv/dt turn-on due to high dv/dt causing capacitive current triggering action.

The last two methods are not recommended for repetitively turning on an SCR because of restricted anode current rise time (di/dt) and magnitude.

To turn off an SCR in an AC phase control circuit is relatively easy. Suppress the gate signal and the reversal of the AC line voltage causes commutation from the conduction state back to the off state. Of course, there are circuits which require sophisticated methods to achieve turn-off commutation such as choppers and inverters. These are available in the literature.

Gate Parameters and Characteristics
Because of the myriad of SCR applications, a dc gate test condition (Figure 2) with a resistive load was chosen to permit both the manufacturer and the user to ascertain basic gate parameters. It was not intended to reflect operational application requirements. These dc gate trigger requirements are normally given on SCR data sheets.

- I_{GT} is a dc gate current which causes the SCR to latch into conduction and remain "on" (hold); referred to as gate trigger current.
- V_{GT} is the dc gate cathode voltage which causes the SCR to latch into conduction and remain "on" (hold); referred to as gate trigger voltage.
- I_{GNT} is a dc gate current which, when applied to the gate cathode terminal, will still permit the SCR to block rated V_{DRM}; referred to as non-trigger gate current.
- V_{GNT} is a dc gate voltage which, when applied to the gate cathode terminal, will still permit the SCR to block rated V_{DRM}; referred to as non-trigger gate voltage.

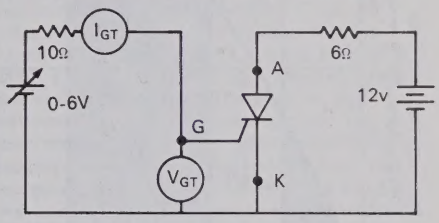

Figure 2. DC Gate Characteristics Test Circuit.

There are other gate parameters which must also be considered and are subsequently covered. They include peak gate trigger current for pulse operation, I_{GTM}; peak and average gate power, P_{GM} and $P_{G(AV)}$; and peak reverse gate voltage, V_{GRM}. The rated values are given in the data sheets.

The maximum gate triggering characteristics for Westinghouse di/namic gate SCR's is given in Figure 3. The di/namic or amplifying gate SCR consists of a pilot and main

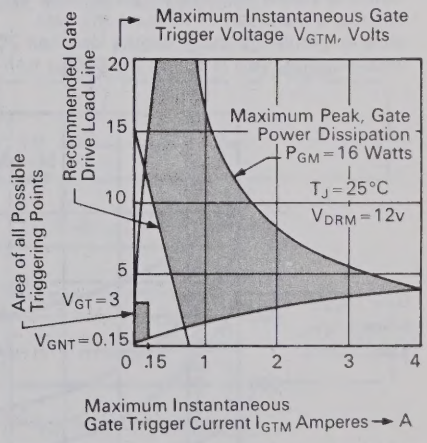

Figure 3. Maximum Gate Triggering Characteristics for Westinghouse di/namic Gate SCR's.

Application Data
SCR GATE TURN-ON CHARACTERISTICS
Gate Drive Requirements

SCR on the same element; this new gating structure provides improved characteristics over previous designs. Note that the ratings are at 25°C and that a recommended load line for moderate di/dt applications is given.

The characteristic effect of junction temperature versus gate trigger current/voltage is depicted in Figure 4 with an SCR I_{GT}=150 ma. Note that as an SCR is heated to 125°C, the required gate current to trigger typically is one-half the 25°C value, and that the —40°C value is approximately twice the 25°C value.

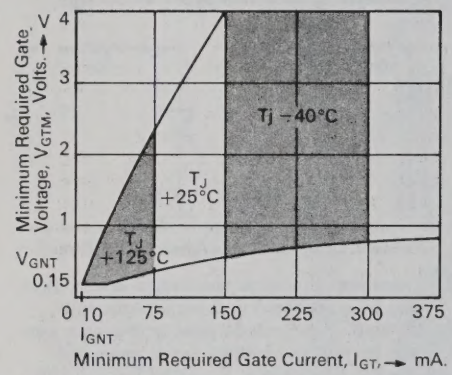

Figure 4. Typical Gate Triggering Range for Various Junction Temperatures.

To relate the measured value of dc gate trigger current to pulsed gate operation required in some applications, the following information is needed and is shown in Figure 5. Whether the SCR design is a conventional center fire gate, di/namic gate, or other, it is necessary to increase the gate drive amplitude for pulse widths less than 20 microseconds. This is due to the charge turn-on concept ($q=\int I_{GT}\,dt_p$) described in the referenced literature. The minimum gate trigger requirements versus pulse widths are given with respect to junction temperature. This insures that the SCR will latch on and remain on (if provided in circuit) but is not the optimum gate drive requirements.

Gate Drive Requirements

The present di/namic gate SCR may be triggered with either Soft Gate Drive or Hard Gate Drive. Predecessor devices with center firing and edge firing gates required hard gate drive to achieve uniform current conduction and low switching losses. However, even with the di/namic gate and newer interdigitated geometries, applications still exist which require hard gate drive.

Hard Gate Drive

Demanding applications where hard gate drive is suggested include inverter and chopper circuits of capacitive type loads where high repetitive di/dt is evident; heavy industrial phase control operation with inductive load (or power factor control) and systems where electrical noise is troublesome requiring noise-immune thyristors and gate signal suppression circuitry (up to I_{GT}). Figure 6 is the suggested Hard Gate Drive for an individual SCR. The cases of anode current conduction interval $\leq$ 20 μs or picket fence gate firing are not shown. Reference must be made to the Minimum Pulsed Gate Trigger Requirements (Figure 5) to obtain the proper value of I_{GT}. This value of I_{GT} is then used for the Hard Gate Drive I_{GTM} determination.

Soft Gate Drive shown in Figure 7 is perfectly adequate for resistive and inductive load applications. In general, a gate drive transistor can be eliminated from the gate firing circuitry, providing a cost reduction. If a snubber network is always available to discharge upon signal initiation, soft gate drive may be adequate even for some high di/dt applications, but further assistance is advised from an application engineer.

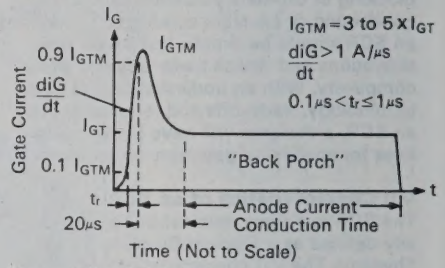

Figure 6. Hard Gate Drive.

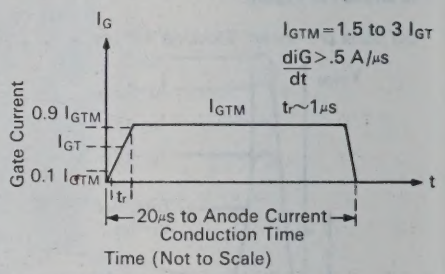

Figure 7. Soft Gate Drive.

Example: A Westinghouse T920 has a data sheet I_{GT}=200 ma @ 25°C. The recommended gate drive, to cover all types of load variations @ T_J=—40°C start-up is as follows:

I_{GT} @ —40°C = 2 x I_{GT} @ 25°C (from Figure 4)
I_{GT} @ —40°C = 400 ma
Hard Gate Drive—I_{GT} = 3.3 to 5 x I_{GT} @ —40°C
Answer I_{GT} = 1.3A peak (Min. value)

The conduction period of the anode current "back porch" must have a gate current no lower than the I_{GT} @ —40°C; i.e., 400 ma to ensure conduction for low power factor loads.

Recommended Gating Practices

A di/namic gate SCR is optimized to provide fast turn-on and low switching losses with a soft gate drive signal. Recognition of situations where di/namic gate action is limited along with a number of recommended design practices are given below.

- Gate the SCR when the anode voltage is positive. Allowing a positive gate while the SCR becomes reverse biased limits device reliability.
- Design the gate firing sequence such that the snubber network across the SCR is charged prior to gate signal. This gives good di/namic gate action.
- If a dc gate signal is used in a multi-phase system a soft gate drive signal does not

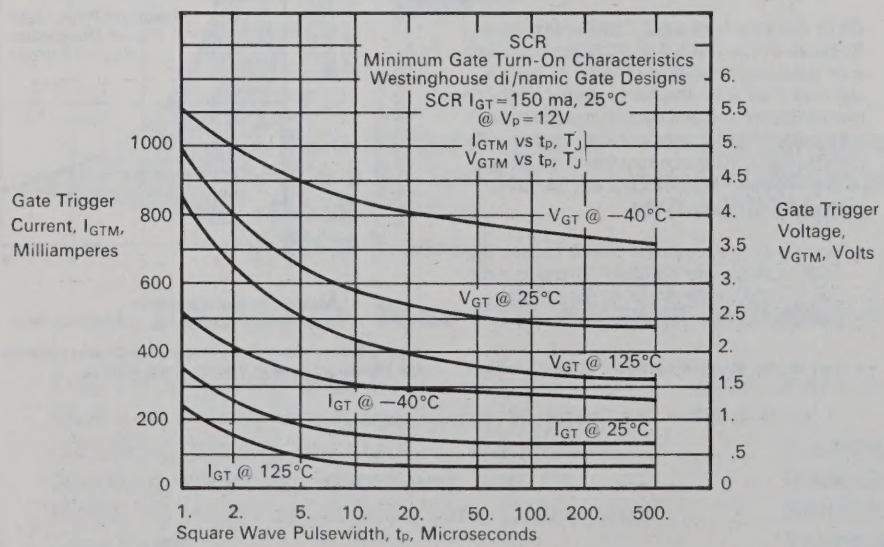

Figure 5. Minimum Pulsed Gate Trigger Requirements.

give good di/namic gate action. No snubber discharge is possible after time zero which results in poor di/namic gate action. In addition, Westinghouse SCR's have high noise-immune characteristics (I_{GNT}) meaning they do not false trigger at very low gate currents. For this particular application hard gate drive is required.

- The gate drive circuitry should have a 1 to 2A average 100V diode in series with the gate and across the gate cathode terminals as shown in Figure 8. These will eliminate two possible failure modes of an SCR. The diodes in series with the gate will prevent negative gate current flow while the diode across the gate cathode limits the reverse gate voltage, V_{GRM}, to ~ 2V by diode clamping.

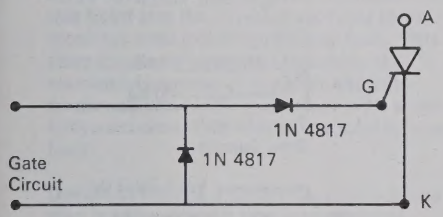

Figure 8. Protected Gate Cathode

- Provide open circuit gate voltage > 20V to prevent gate drive extinction. The instantaneous gate cathode voltage can exceed the source voltage in high di/dt applications.

- Inductive loads can be troublesome if the gate drive is insufficient in amplitude or width. Existing recommended practice is the use of the "picket fence" or hard gate drive. A picket fence is a high frequency gate signal varying from 1 to 15KHz, 200μs to 50μs wide within a 60Hz envelope such that the SCR is continuously gated. The average gate current rating is maintained. In hard gate drive circuits, the "back porch" anticipates worse-case power factor; making the gate pulse width wide enough to ensure SCR latching and holding.

- To prevent noise pickup in the gate potential connections, twist together the gate cathode potential leads of the SCR and use either a twisted wire pair from the gate pulse amplifiers circuit or a coax-type shielded cable. Locate the wires as close as possible to the SCR but away from magnetics or high current carrying members in the circuit. Of course, the gate cathode lead lengths should be as short as possible.

- To minimize △ delay time variations between SCR's, use hard gate drive with as high a gate current risetime (di_G/dt) as possible; ref. Figure 6.

- Always use a resistor in series with each gate lead if triggering more than one SCR from the same source. Generally, 10 to 25Ω is used to diminish input gate cathode impedance variations.

- Use single point triggering if gating more than one device from the same source.

- If highest total circuit reliability is desired, a power burn-in of the complete gate firing board at rated temperatures and power will eliminate weak components and infant mortality.

Series Operation

Present application techniques are such that, in many designs, circuit applications exceed device blocking capabilities. For this reason, series connected SCR applications have been, and are prevalent. Figure 9 shows a typical circuit connection, including the compensating components required for proper operation. In such a series connection the last device to turn on may be subject to an overvoltage and dissipates the most energy. A high drive gate signal from a single source is required to minimize delay times and switching losses. The resistors R_B are for static voltage balancing due to blocking voltage, leakage current differences. The snubber capacitor C is not only for dv/dt but also for Q_{RR} variations.

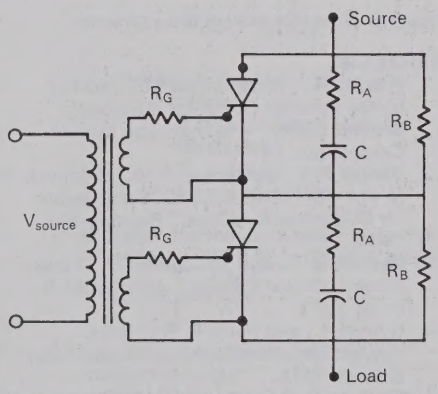

Figure 9. Typical Series Connection with Single Point Triggering.

It should also be noted that the gate circuitry employs individual resistors. To neglect this point is dangerous, since one low impedance gate consumes an excess of the available energy by voltage clamping of the transformer, thus reducing the energy available to the other devices and possibly causing overvoltage destruction of the device with the maximum delay. In such applications, a good overdrive gate signal is recommended.

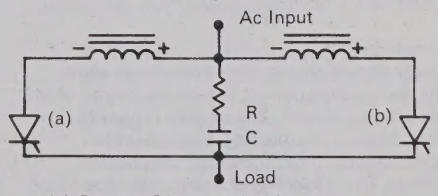
One should specify matched △ delay times and △ Q_{RR} (if not diode clamped) for each series connected group of SCR's to optimize voltage sharing.

Parallel Operation

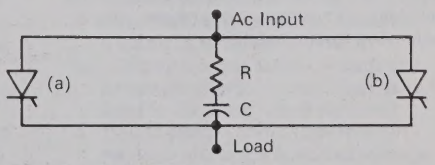
Discrete SCR's must be paralleled because they lack the required current handling capability, redundancy is required or because reduced junction temperature operation is desired. It is understood that the required type of gate drive circuit is dependent upon the particular circuit and load characteristics.

A specific gate firing problem is encountered with parallel operation of devices. In situations where anode reactors are employed, as shown in Figure 10, care should be exercised because as device "a" turns on, its voltage is supported by the reactor. Until the slow device "b" turns on, no current, except magnetizing current, flows. Therefore, device "a" has low turn-on losses. Device "b" on the other hand has the circuit voltage plus the transformed voltage across it while switching half the load current, and so is stressed harder due to delay variations. Therefore, in this instance the designer should consider the delay variations in gate pulse amplifier design, assuming single point triggering. It must be recognized that with a di/namic gate device and low magnetizing current (~I_L), di/namic gate action may not be achieved and high gate drive is recommended.

The necessity for economy sometimes dictates the operation of thyristors without balancing components, as illustrated in Figure 10(b). Unlike the previously described situation, with balancing reactors, device "a" turns on first and is more severely stressed as it must switch both the R-C network energy and the load current. If the load is capacitive or resistive a di/dt problem may exist. The combination of di/dt, device "b" turn-on with very low anode voltages, and long delay times, dictates hard gate drive.



(a) Reactor Current Balancing



(b) No External Balancing

Figure 10. Parallel Operation of Thyristors.

It is also wise in this type of operation to select device characteristics which provide matching voltage drops and turn-on times. In inverter or commutating SCR applications, the di/namic forward voltage drop matching permits current sharing while steady state voltage drop matching is not necessary.

Application Data
SCR GATE TURN-ON CHARACTERISTICS
Gate Drive Requirements

Gate Firing Circuits

A gate trigger circuit can become quite sophisticated such as in an inverter application. Trigger logic circuits have been designed to do many things—

- Trigger the proper SCR's.
- Suppress the gate at overtemperature conditions.
- Crowbar (trigger) or suppress at fault conditions or overvoltage.
- Not trigger at low gate signal levels or predetermined pulse widths.

These type of circuits require design time and in many cases practical experience. If your experience or time is limited, consider the commercial gate firing circuit manufacturers to implement your required SCR circuit. Shown in Figure 11 are three examples of an SCR's hard gate firing circuit for phase control operation.

In the first circuit, a Shockley diode (4E20-8) provides the trigger pulse by voltage breakover, with AC line synchronization on the primary. In the second circuit, the Westinghouse T507 or other fast turn-on SCR is the trigger pulse, which can be gated within any point of the positive AC voltage. The negative AC voltage causes the SCR to line commutate off. The DC circuit uses a transistor to trigger, since an SCR in this circuit would not naturally commutate off. In all three circuits, the negative gate voltage is clamped by the diode across the gate cathode terminals. Other gate firing circuits are available in the Westinghouse SCR Designer's Handbook and those of other manufacturers.

Summary

The information provided herein will allow the designer or user to assess the merits of a gate trigger circuit. It is important that the gate drive circuit provide a signal which compensates for temperature and circuit effects. The reliability of a circuit is dependent upon every item within it. A proper gate drive signal will not guarantee improved circuit reliability but certainly is a proper step in achieving total reliability.

THYRISTOR SURGE SUPRESSION RATINGS
Phase Control SCR'S

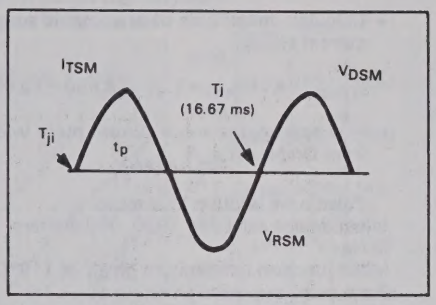
During the design of any power circuit incorporating thyristors, the designer is faced with choosing between several techniques for protecting the thyristors from load induced faults which would subject them to inordinately high levels of forward current. Many of these faults are of short duration and self-clearing. Conventional fault clearing techniques employing breakers or fuses are costly to maintain as they require varying periods of "downtime" either to reset the breakers or replace blown fuses. A better approach to limiting faults of this nature is surge suppression.

Thyristor Surge Suppression

Surge suppression is a fault clearing technique utilized in AC circuits in which the thyristor "rides thru" the first half cycle of surge current. The gate drive is inhibited at this point and the thyristor recovers to the blocking state isolating the load fault. Gate drive can be re-instituted following the successful clearing of the fault allowing continued use of the equipment with essentially zero downtime due to the load induced fault.

Design of circuits employing surge suppression is more difficult than conventional designs for several reasons. Fault sensing logic must be employed to sense and clear the fault and then perhaps automatically re-institute circuit operation. The exact magnitude of the worst case current fault must be known to properly coordinate the thyristors. Of prime importance, a definitive set of surge suppression ratings must be available for the thyristors to facilitate proper derating for reliable operation.

To aid in your design of a surge suppression circuit, a number of graphs have been developed. The first graph A has been designed to facilitate the determination of the magnitude and width of a fault current pulse given the ratio of resistance (R) to inductive reactance (X_L) of the circuit during a fault. Graphs B-1 through B-17 for Westinghouse phase control thyristors give the maximum permissible single cycle surge current that can be reliably utilized in a surge suppression circuit. These current levels are presented as functions of the base width and initial peak junction temperature as the figure illustrates. Graph C gives the voltage rating factor applicable to all Westinghouse phase control devices. Their use is outlined and an illustrative example is as follows:



Procedural Outline

1. Determination of fault current magnitude and pulse width.
   Determine the equivalent resistance
   a. (R) and inductive reactance (X_L) from detailed analysis of voltage source and circuit loop impedances.
   b. Determine the offset factor, K, from the graph A, given the value of $\frac{R}{X_L}$.
   Then $I_{T(asm)} = K \times I_{T(sm)}$ where:
   $I_{T(asm)}$ is the peak value of asymmetric surge current
   $I_{T(sm)}$ is the peak value of symmetric surge current given by:

$$I_{T(sm)} = \frac{V}{(R^2 + X_L^2)^{1/2}}$$

   Where: V is the peak open circuit voltage.
   R is the value of circuit resistance.
   X_L is the value of circuit inductive reactance.

   c. Determine the asymmetric surge current base width from Graph A given the value of $\frac{R}{X_L}$.

2. Selection of proper thyristor for an anticipated surge.
   a. Select the proper family of thyristors suited to the specified operating current—voltage—mechanical configuration and cooling requirements of the equipment. Refer to the Westinghouse Short Form Catalog (54-000) or specific data sheets for this information.
   b. Refer to the appropriate *Surge Suppression Rating* Graph B-1 through B-17 for the specific thyristor selected in 2a.
      (1) Calculate or estimate the peak junction temperature of the thyristor prior to the anticipated surge. Worst case will be 125°C.
      (2) On the Surge Suppression Rating graph B-1 through B-17, locate the specific ordinate scale pertaining to the anticipated surge current pulse width.
      (3) Locate the specific magnitude of surge current on this scale.
      (4) Move horizontally on this value of surge current until you intersect the peak initial junction temperature curve as determined in 2.b.1.
      (5) Read the peak junction temperature from the abscissa scale.
      (6) Refer to Graph C for the *Voltage Rating Factor.* Find the value of the maximum junction temperature following surge given in 2.b.5 on the abscissa scale. Follow this value of temperature vertically until you intersect the "standard" curve. The value of the Voltage Rating Factor, F, corresponding to this intersection is the minimum F factor which can be used to establish the device voltage rating by the following expression.

$$V_{Rating} = F \times V_P$$

      Where:
      - V_{Rating} is the minimum rated voltage for the thyristor, V_{DRM} and V_{RRM}.
      - F is the voltage rating factor.
      - V_P is the peak forward voltage seen by the thyristor following a surge.

3. If the voltage rating derived above is greater than that attainable for the device in question there are several options open:
   a. Repeat 6 using the "selected" curve. If an acceptable rating is attained, a device may be specially selected and tested by the manufacturer to perform at the specified operating levels. Contact your Westinghouse Applications engineer for details if you require a specially selected device.
   b. A higher current rated thyristor can be specified and the calculations outlined in 2b-1 thru 2b-6 repeated.
   c. Two thyristors can be operated in series to attain the specified voltage rating.

Application Data
THYRISTOR SURGE SUPPRESSION RATINGS
Phase Control SCR'S

Design Example
Given:
- Maximum junction temperature prior to surge, T_{ji}=110°C.
- Circuit equivalent resistance, R=.01 ohms.
- Circuit equivalent inductive reactance, X_L=.025 ohms.
- Peak open circuit voltage, V_P=400V.
- Assume a 1000V, T920 type thyristor will be used for this application for steady state current and reliable voltage derating requirements.

Find:
Magnitude and width of fault current pulse.
Acceptable device rating for this application.
Procedure:

$$\frac{R}{X_L}\ \text{ratio}=\frac{.01}{.025}=0.40$$

From Graph A find the offset factor, K=1.28
- Calculate magnitude of symmetric surge current $I_{T(sm)}$.

$$I_{T(sm)}=\frac{V}{(R^2+X_L^2)^{1/2}}=\frac{400}{[(.01)^2+(.025)^2]^{1/2}}$$

$$=14{,}855\text{A}$$

- Calculate magnitude of asymmetric surge current $I_{T(asm)}$.

$$I_{T(asm)}=K\cdot I_{T(sm)}=1.28\cdot 14{,}860=19{,}000\text{A}$$

- Find asymmetric surge current pulse width from Graph A for $\frac{R}{X_L}=.40$.

Pulse base width=11.9 msec.
Initial device selection T920, 900 ampere device.
Initial junction temperature given as 110°C.
From surge suppression rating curve for T920—09 (Graph B-16).
12 msec. ordinate scale—19000A peak using T_{ji} curve for 110°C.
Peak T_j=173°C from graph.
Examining the Voltage Rating Factor curve for a standard device at 173°C, *NO* F factor is available in the standard rating. The 900 ampere standard device cannot be used under the stated conditions.
First Option:
Evaluate the T920—1000 ampere device.

T_{ji}=110°C

from surge suppression curve for T920—10 (Graph B-17).
12 msec. ordinate scale—19,000A using peak T_{ji}=110°C curve.

Peak T_j=163°C

Using the Voltage Rating Factor curve for a standard device at Peak T_j=163°C,

F=3.2

$V_{Rating}=F\cdot V_P=3.2\cdot 400=1280$ volts

A standard 1300 volt—1000 ampere T920 thyristor fulfills the minimum requirement for this application.

Second Option:
Using the special selection curve of Graph C for T_j=173°C; F=2.6.

$V_{Rating}=2.6\times 400=1040$ V.

A specially selected 1100 volt—900 ampere T920 thyristor may also be used.

Conclusion

A detailed procedure has been outlined which will aid in specifying a device for a given surge suppression requirement. The surge suppression ratings arrived at by this technique are intended to be maximum ratings similar to the maximum blocking voltage and conduction current specifications on device data sheets. As such, a certain degree of derating from this maximum operating condition would greatly increase the reliability of operation. This derating is intended to buffer the detrimental effects of variations in circuit parameters from the values used in the determination of the device specifications.

In addition, care must be taken throughout the design of the equipment. The gate drives must be well shielded so as not to present appreciable noise currents to the thyristor during the surge suppression interval. These noise currents could cause retriggering due to the increased gate sensitivity of the device at the high junction temperature following a surge.

RC dv/dt suppression networks are required to hold the reapplied dv/dt to less than the data sheet rating to prevent dv/dt triggering following the surge. This is the predominant surge suppression failure mode and thus great care should be taken in the suppression network design.

Secondary fault protection techniques must be employed in the event the thyristor fails to successfully suppress the fault. This is usually provided by slow speed fuses or circuit breakers.

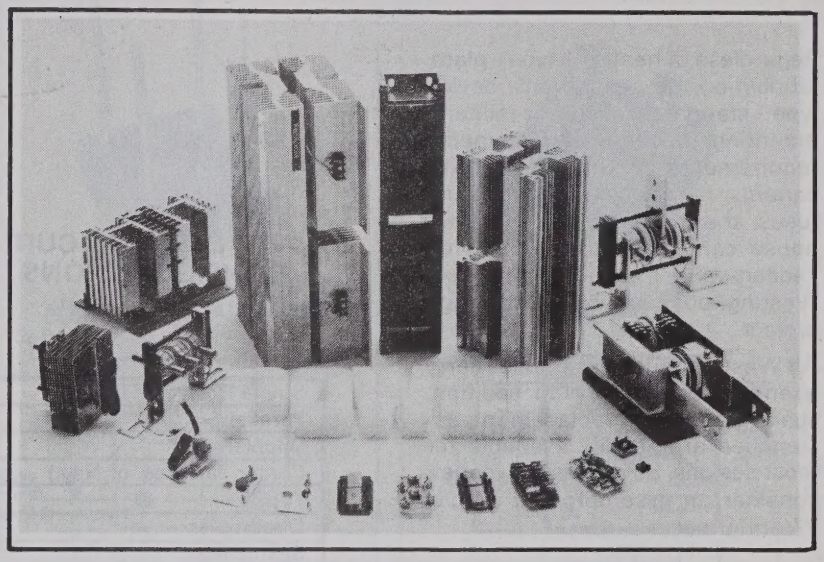
ASSEMBLIES

INTRODUCTION

Westinghouse has an extensive line of assembly capabilities with over twenty years of design experience. These products include Modular Bridges, Gold Line-Stud Mount, Air and Liquid Cooled-Disc, High Voltage Stacks, and Custom Designs in a variety of circuit configurations as identified on the following pages.

Westinghouse assemblies offer you savings in money, manpower, and time. Pre-engineered modular designs are available wth expert application assistance. All devices and heat sinks are thermally matched for optimum performance with guarteed ratings and are 100% factory tested. Buying assemblies rather than discrete components minimizes or eliminates tooling and set up charges and means single supplier contact for negotiating, purchasing, and expediting materials. Multiple incoming inspections, inventory investment, assembly time, and other handling costs are reduced. Thus, buying assemblies can save time and money while allowing a company to use its manpower and resources on programs that offer a greater return on investment. Buyers of assemblies also benefit by buying products which utilize the latest assembly techniques as well as those that incorporate the state-of-the-art in power semiconductors and heat sinks.

In addition to the industry's broadest line of "catalog" assemblies, Wesinghouse can offer custom designs to meet virtually any requirement - consumer, industrial, or military. As a semiconductor manufacturer and a knowledgeable assembly supplier who deals with numerous materials and vendors worldwide, Westinghouse can help you minimize your total system cost by optimizing your custom design.



ASSEMBLY PRODUCT INDEX

	PRODUCT FAMILY	PAGE
M	MODULAR BRIDGES, SINGLE PHASE RECTIIFER 2-25A/50-1000V	A3
	Economical, electrically isolated designs provide high surge ratings and small size for applications requiring easy hookup and reductions in assembly time.	
G	GOLD LINE 12-1670A/100-2000V	A5
	A complete product line of stud mount rectifier and/or SCR assemblies simplifies any design selection because of circuit, mounting and electrical mounting and electrical variations that are available from standard designs.	
P	AIR AND LIQUID COOLED DISC 197-13,580A/100-4000V	A37
	Variations of six heat sink designs (three extrusions and three castings) provide a building block approach to the mounting and cooling of a complete line of disc rectifiers and/or SCR's.	
S	HIGH VOLTAGE STACK, CHANNEL DESIGN .5-324A/1-688KV	A69
	Fully compensated rectifier modules in conjunction with a varilength mounting channel provide a method of obtaining custom designs from standardized components with very high packaging densities.	
H	HIGH VOLTAGE STACK, PLATE DESIGN 6-450A/2-72KV	A76
	Provides a viable base design for very high current and high voltage rectifier design combinations requiring repetitive surge capabilities and high reliability.	
	SINKS AND KITS	A65
	Sinks developed by Westinghouse are offered in complete kits with all necessary hardware supplied to mount and assemble disc power semiconductors. Extrusions designed for cooling large area power semiconductors are compatible with special fabrications.	

ASSEMBLIES

Regardless of heat sink type - plate, fabrication, or extrusion; device type - standard, special, or military; mounting, cooling, and clamping requirements; or other special components - resistors, capacitors, fuses, thermostats, etc., Westinghouse can help. To get this free "added value" service, simply call Westinghouse on your next design project.

All Westinghouse assemblies carry a one year warranty. In addition, spare parts and replacement assemblies are readily available for most designs. Save time and money; consider an assembly and specify Westinghouse!

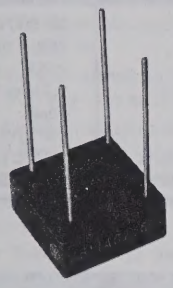
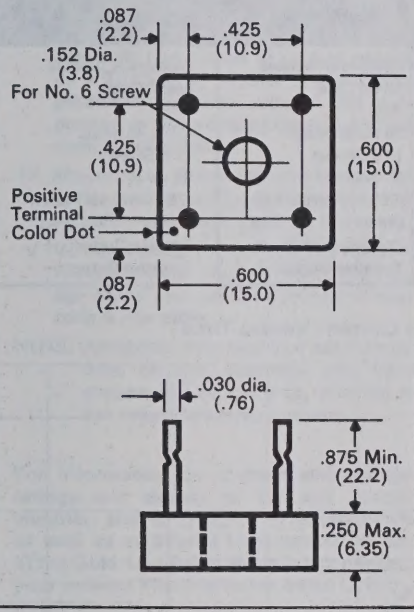
Modular ASSEMBLIES MB11, MB12

2-25 Amp. Rectifier

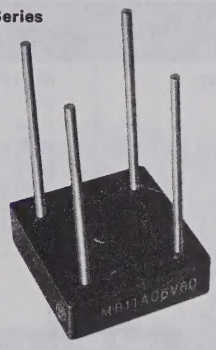
Dimensions: Inches (Millimeters)

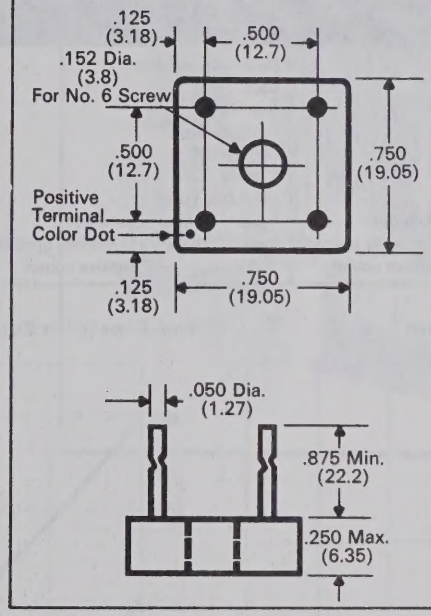
MB11A02 Series



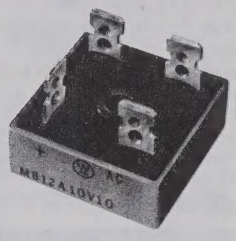


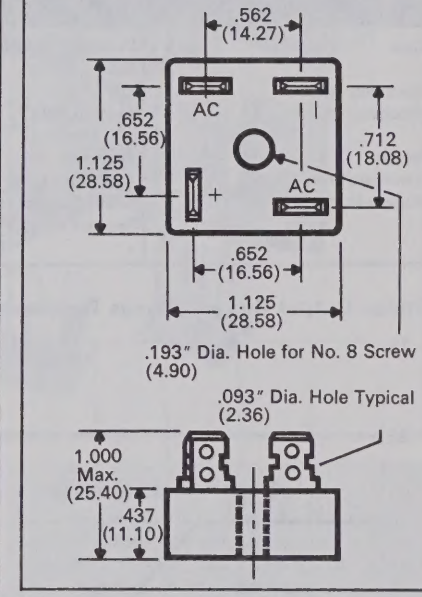
MB11A06 Series





MB12A10 & MB12A25 Series





Features:

- Single phase bridge circuit
- Positive terminal polarity key (MB12)
- Electrically isolated case
- Low V_f, low leakage
- High surge current ratings

Applications:

- Motor control, AC to DC converters
- Power supplies, battery chargers

Benefits:

- Economy • Availability
- Easy assembly hook-up
- 25 to 50% reduction in assembly time

Module:	Assembly/Cell Voltage Rating	Voltage Code
MB11A02 MB11A06 MB12A10 MB12A25	50	V05
	100	V10
	200	V20
	300	V30
	400	V40
	600	V60
	800	V80
	1000	W10

Ordering Guide

To order a Westinghouse Modular Assembly simply add the appropriate voltage code suffix from the table to the basic type number of the assembly you have selected. For example, to order the assembly MB12A25 with a 400 Volt rating, add the voltage code suffix—V40. Now the complete ten digit type number description is MB12A25V40.

Stud Mount ASSEMBLIES Gold Line

How to Select an Assembly

I. Circuit Funtion

A. Rectifier (contains rectifiers only) — Go to Page A6

B. Half Control (contains both rectifiers and SCR's) — Go to Page A16

C. Full Control (contains SCR's only) — Go to Page A24

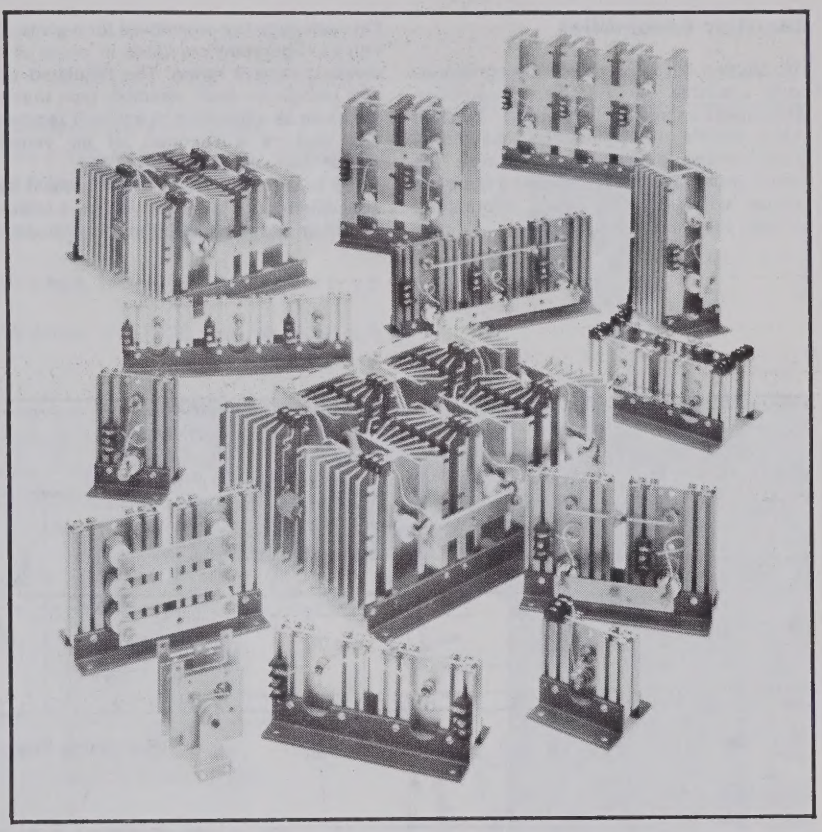
II. Circuit Configuration — Select the configuration desired and then turn to the page number referenced.

III. Current Rating — The assemblies are listed in order of increasing current rating on each page. Select the one that best meets your requirements. Each assembly has a table of current ratings as a function of various ambient temperatures, air flow velocity and conduction or delay angles for half and full control assemblies.

IV. Mounting — Select the type number for either floor or wall mounting. Most assemblies offer both types of mounting.

V. Voltage Rating — Now from the range of voltage ratings shown, select the voltage rating you require from the voltage code suffix table.

NOTE: Additional electrical and mechanical data on the assembly you have chosen can be found by referring to the respective key numbers.



For information on current and voltage ratings not shown or for any special electrical and/or mechanical requirements as well as additional information on any of the Gold-Line Assemblies listed, contact your nearest Westinghouse Sales Office.

Features

- Pre-engineered Design
- Fully Tested Assemblies
- Guaranteed Assembly Ratings
- Easy to Read Rating Charts
- General Recommendations for Fuses, Voltraps, Gate Drives, R-C Networks
- Complete Information for Assembly Application
- Value Engineered Design
- Compact Size
- Light Weight
- Low Cost
- Full Range of Current and Voltage Ratings
- All Standard Circuit Configurations Available
- Most Assemblies Built from Stock
- Gold Chromate Finish
- Insulated Mounting
- JEDEC and MIL Approved Devices Available for Most Designs
- Resistor/Capacitor Networks and other Special Frame Modifications Available.

Assembly Ordering Guide

To order a Westinghouse Gold-Line Assembly, simply add the appropriate voltage code suffix from the table below to the basic Type number of the assembly you have selected. For example, to order the assembly – GB23A41 with a 600 volt rating, add the voltage code suffix – V60. Now the complete ten digit type number description is GB23A41V60.

Voltage Code Suffix Table

Assembly/Device Voltage Rating	Voltage Code
100	V10
200	V20
300	V30
400	V40
600	V60
800	V80
1000	W10
1200	W12
1400	W14
1600	W16
2000	W20

Rectifier Assemblies

This section describes the circuit configurations available for Rectifier Assemblies. (assemblies using rectifiers only). The chart below shows the schematics, waveform, recommended diode voltage ratings, the basic current ratings available, and the page number where specific rating information for each assembly can be found.

On each page the assemblies for a given circuit configuration are listed in order of increasing current rating. The tabulated current ratings for each assembly type number are given as a function of ambient temperature and as a function of air velocity (linear feet per minute – LFM).
Refer to the mechanical and electrical keys specified for the assembly you have selected to obtain assembly weight and dimensions and other electrical data and recommendations.

Circuit		Assembly Output				
Configuration	Schematic	Wave Form	E_D = Avg. Voltage	E_a = RMS Voltage	Ripple (%)	I_F(AVG)/RE
R – Single Rectifier			.45 E_{RMS}	.707 E_{RMS}	121	I_D
D – Doubler		(See Single Phase Bridge "B" or Three Phase "E").				
N – Neg Center Tap			.900 E_{RMS}	1.0 E_{RMS}	48	½I_D
C – Pos Center Tap			.900 E_{RMS}	1.0 E_{RMS}	48	½I_D
B – Single Phase Bridge			.900 E_{RMS}	1.0 E_{RMS}	48	½I_D
E – Three Phase Bridge			1.350 E_{RMS}	1.351 E_{RMS}	4	⅓I_D
S – Six Phase Star			1.350 E_{RMS}	1.351 E_{RMS}	4	⅙I_D
Y – Three Phase Wye (with Interphase Transformer)			1.170 E_{RMS}	1.171 E_{RMS}	4	⅙I_D

Description of Rectifier Assemblies Pictured on the Right

I. Westinghouse GE11A61, 3ϕ Bridge, 35-61 Amps, 100-800 Volts on 3 x 3 plates.
II. Westinghouse GE15B30, 3ϕ Bridge, 100-300 Amps, 100-1600 Volts on 1¼ x 4 x 5 heat sinks.
III. Westinghouse GE16B45, 3ϕ Bridge, 225-450 Amps, 100-1600 Volts on 4 x 4 x 5 heat sinks.
IV. Westinghouse GE19B53, 3ϕ Bridge, 280-530 Amps, 100-2000 Volts on 5 x 5 x 6 heat sinks.
V. Westinghouse GE19B83, 3ϕ Bridge, 520-830 Amps, 100-2000 Volts on 5 x 5 x 6 heat sinks.

Actual Diode Peak Reverse Voltage	Recommended Rectifier Diode Repetitive Voltage Rating	Available Assemblies: Output Current Ratings (Amperes) AVG — Natural Convection @ 40°C	Available Assemblies: Output Current Ratings (Amperes) AVG — Forced Convection @40°C & 1000 LFM	For Specific Rating Info See Page
1.41 E_{RMS} or π E_D	2.8 E_{RMS} or 6.28 E_D	12 to 190	22 to 300	A8
		12 to 120	45 to 610	A9
2.828 E_{RMS} or π E_D	5.7 E_{RMS} or 6.28 E_D	26 to 380	45 to 610	A11
2.828 E_{RMS} or π E_D	5.7 E_{RMS} or 6.28 E_D	26 to 380	45 to 610	A10
1.414 E_{RMS} or 1.57 E_D	2.8 E_{RMS} or 3.2 E_D	26 to 380	45 to 610	A12
1.414 E_{RMS} or 1.05 E_D	2.8 E_{RMS} or 2.1 E_D	35 to 520	61 to 830	A13
2.828 E_{RMS} or 2.1 E_D	5.7 E_{RMS} or 4.2 E_D	57 to 850	100 to 1360	A14
2.45 E_{RMS} or 2.1 E_D	4.9 E_{RMS} or 4.2 E_D	70 to 1050	120 to 1670	A15

Half Control Assemblies

This section describes the standard circuit configurations available for Half Control Assemblies (assemblies using both rectifiers and SCR's). The chart below shows the schematics, waveform, recommended SCR and diode voltage ratings, the basic current ratings available, and the page number where specific rating information for each assembly can be found.

On each page the assemblies for a given circuit configuration are listed in order of increasing current rating. The tabulated current ratings for each assembly type number are given as a function of ambient temperature, as a function of the conduction or delay angle, and as a function of the air velocity (linear feet per minute – LFM). The conduction angle is defined as the number of electrical degrees the SCR conducts current. The delay angle is defined as the number of electrical degrees the gate trigger pulse is delayed from the time the anode voltage on the SCR starts positive. Refer to the mechanical and electrical keys specified for the assembly you have selected to obtain assembly weight and dimensions and other electrical data and recommendations.

Circuit		Assembly Output			
Configuration	Schematic	Waveform	Maximum Voltage E_d=Avg. E_a=RMS	Maximum SCR Voltage	Maximum Diode Voltage
D – Doubler		(See: Single Phase Bridge "B" or Three Phase Bridge "E")			
A – Single Phase AC Switch			$E_a = E_{RMS}$	1.4 E_{RMS}	1.4 E_{RMS}
B – Single Phase Bridge			E_d=.90 E_{RMS}	1.4 E_{RMS}	1.4 E_{RMS}
E – Three Phase Bridge			E_d=1.35 E_{RMS}	2.45 E_{RMS}	2.45 E_{RMS}
F – Three Phase AC Switch			$E_a = E_{RMS}$	1.4 E_{RMS}	1.4 E_{RMS}

Description of Half Control Assemblies Pictured on the Right

- **I** Westinghouse GA28B32, 1ϕ AC Switch 180-320 Amps, 100-1600 Volts on 4 x 4 x 9 heat sinks.
- **II** Westinghouse GB28B29, 1ϕ Bridge, 161-290 Amps, 100-1600 Volts on 4 x 4 x 9 heat sinks.
- **III** Westinghouse GE28B42, 3ϕ Bridge, 232-420 Amps, 100-1600 Volts on 4 x 4 x 9 heat sinks.
- **IV** Westinghouse GE24B11, 3ϕ Bridge 54-110 Amps, 100-1000 Volts on 1¼ x 4 x 5 heat sinks.
- **V** Westinghouse GF24A89, 3ϕ AC Switch 42-89 Amps, 100-1000 Volts on 1¼ x 4 x 5 heat sinks.

Recommended SCR & Diode Voltage Rating	Available Assemblies: Output Current Ratings (Amperes) Natural Convection at 40°C	Available Assemblies: Output Current Ratings (Amperes) Forced Convection at 40°C & 1000 LFM	For Specific Rating Info See Page
	12 to 77	19 to 140	A18
2.8 E_{RMS}	28 RMS to 180 RMS	46 RMS to 320 RMS	A19
2.8 E_{RMS} or 3.9 E_d	26 to 161	41 to 290	A20
4.9 E_{RMS} or 2.1 E_d	37 to 232	58 to 420	A21
2.8 E_{RMS}	28 RMS to 180 RMS	46 RMS to 320 RMS	A22

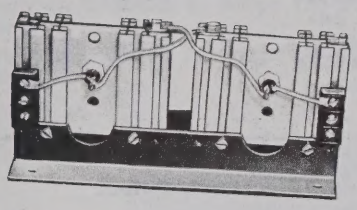
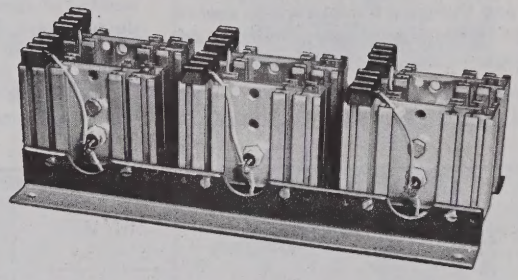
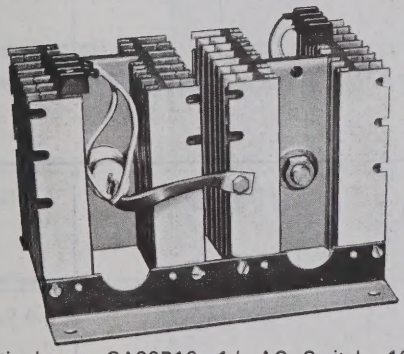
Full Control Assemblies



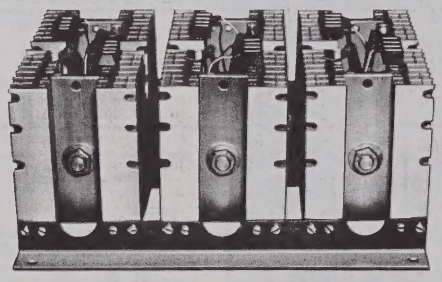
I Westinghouse GA33A49, 1ϕ AC Switch 34-49 Amps, 100-1200 Volts on 1¼ x 4 x 3 heat sinks.



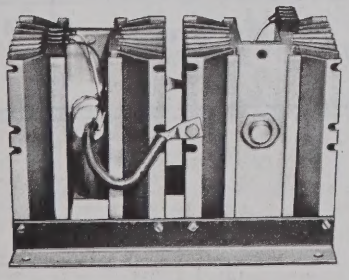
IV Westinghouse GF33A49, 3ϕ AC Switch, 34-49 Amps, 100-1200 Volts on 1¼ x 4 x 3 heat sinks.



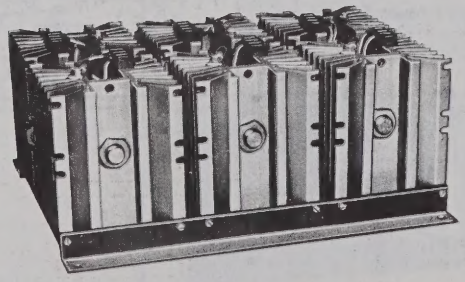
II Westinghouse GA36B16, 1ϕ AC Switch, 104-160 Amps, 100-1200 Volts on 4 x 4 x 5 heat sinks.



V Westinghouse GF36B16, 3ϕ AC Switch 104-160 Amps, 100-1200 Volts on 4 x 4 x 5 heat sinks.



III Westinghouse GA39B34, 1ϕ AC Switch 222-340 Amps, 100-1600 Volts on 5 x 5 x 6 heat sinks.



VI Westinghouse GF39B34, 3ϕ AC Switch 222-340 Amps, 100-1600 Volts on 5 x 5 x 6 heat sinks.

Full Control Assemblies

This section describes the standard circuit configurations available for Full Control Assemblies (assemblies using SCR's only). The chart below shows the schematics, waveform, recommended SCR voltage ratings, the basic current ratings available, and the page number where specific rating information for each assembly can be found.

On each page the assemblies for a given circuit configuration are listed in order of increasing current rating. The tabulated current ratings for each assembly type number are given as a function of ambient temperature, as a function of the conduction or delay angle, and as a function of the air velocity (linear feet per minute – LFM). The conduction angle is defined as the number of electrical degrees the SCR conducts current. The delay angle is defined as the number of electrical degrees the gate trigger pulse is delayed from the time the anode voltage on the SCR starts positive. Refer to the mechanical and electrical keys specified for the assembly you have selected to obtain assembly weight and dimensions and other electrical data and recommendations.

Circuit		Assembly Output		
Configuration	Schematic	Waveform	Maximum Voltage E_d=Avg. E_a=RMS	Maximum SCR Voltage
T – Single SCR			E_d=.45 E_{RMS} E_a=.707 E_{RMS}	1.4 E_{RMS}
D – Doubler		(See: Single Phase Bridge "B" or Three Phase Bridge "E")		
A – Single Phase AC Switch			E_a=E_{RMS}	1.4 E_{RMS}
B – Single Phase Bridge			E_d=.90 E_{RMS}	1.4 E_{RMS}
E – Three Phase Bridge			E_d=1.35 E_{RMS}	2.45 E_{RMS}
F – Three Phase AC Switch			E_a=E_{RMS}	1.4 E_{RMS}

Description of Full Control Assemblies Pictured on the Right

VII. Westinghouse GB33A44, 1ϕ Bridge, 34-44 Amps, 100-1200 Volts on 1¼ x 4 x 3 heat sinks.

VIII. Westinghouse GB36B14, 1ϕ Bridge, 93-140 Amps, 100-1200 Volts on 4 x 4 x 5 heat sinks.

IX. Westinghouse GB39B31, 1ϕ Bridge, 196-310 Amps, 100-1600 Volts on 5 x 5 x 6 heat sinks.

X. Westinghouse GE36B20, 3ϕ Bridge, 135-200 Amps, 100-1200 Volts on 4 x 4 x 5 heat sinks.

XI. Westinghouse GE39B44, 3ϕ Bridge, 285-440 Amps, 100-1600 Volts on 5 x 5 x 6 heat sinks.

Electrical Data

Tables I and II provide General Recommendations for Transient Voltage Protection. Tables III and IV must be used in conjunction with the electrical key specified with each of the assembly type numbers. These tables cover non-repetitive surge ratings, I^2t ratings, general fuse recommendations, recommended gate drive requirements, and recommended RC dv/dt networks for the devices used in the Gold Line Assemblies.

Circuit conditions and economics will dictate which protective devices, if any, are necessary for reliable operation.

Table I General Recommendations for Voltrap® Transient Voltage Suppression for Gold-Line Assemblies

This table can be used as a general guide with any Gold Line Assembly. Knowing the Assembly Input Power Transformer KVA and the Secondary Line to Line Voltage, one can obtain the size of the Voltrap® required. The Voltraps® should be connected across each device with the shortest lead lengths practical. For more information regarding the selection and application of Westinghouse Voltraps®, send for T.D. 16-435, pp. 1-14 – Westinghouse Electric Co., General Control Division, Buffalo, N. Y. 14240.

Assembly Input Power Transformer KVA	Secondary Line to Line Voltages (Volts)					
	12	24	60	120	240	480
1	S04	S03	S01	S01	S01	S01
2	S05	S04	S02	S01	S01	S01

100	..	..	..	S05	S04	S03
200	..	..	..	..	S05	S04
500	..	..	..	..	..	S05

Table II General Recommendations for RC Transient Voltage Suppression Across the DC Output Terminals for Gold-Line Assemblies

This table can be used as a general guide with any Gold Line Assembly. R-C networks are generally used when Voltraps® are not considered economical. Only carbon or non-inductive wound power resistors and extended foil or computer grade electrolytic capacitors should be used. The R-C network with the shortest lead lengths possible should be connected across the DC Output Terminals of the Rectifier Assembly.

R = Resistor (ohms)
P = Power Rating of Resistor (watts)
C = Capacitor (microfarads)
V = Voltage Rating of Capacitor (volts)

General recommendations assume that the transformer and line inductance are less than $R^2C/4$.

Assembly DC Output Current Amperes		Secondary Line to Line Voltage (Volts)

Table III Electrical Data and General Fuse Recommendations for Rectifier Gold-Line Assemblies

This chart lists the non-repetitive 1-3-5-10 cycle surge current ratings and I^2t ratings for the rectifiers used in the Gold Line Assemblies. In addition, general fuse recommendations are presented. Fuses must be mounted in series with each device. The numbers listed in the table are Chase-Shawmut (Newburyport, Mass.) Form 101 Amp-Trap®. Equivalent fuse types are available from several companies. A partial listing of these companies include:

1. Bussmann Mfg. Div.
   McGraw Edison Co.
   St. Louis, Missouri 63107
2. The Carbone Corporation
   Boonton, New Jersey 07005
3. English Electric Co., Limited
   Fusegear Division
   Liverpool, England

Electrical Data Number	I_{FSM} Surge (Amperes)				I^2t (Amp²–Sec)	Line Voltage (Volts)	Fuse

Table IV Electrical Data and General Gate Drive, Fuse, and RC dv/dt Network Recommendations for Half and Full Control Gold Line Assemblies

This table lists the non-repetitive 1-3-5-10 cycle surge current ratings, I^2t ratings and general fuse recommendations for Half Control and Full Control Gold Line Assemblies. The fuse types shown are Chase-Shawmut Form 101 Amp-Trap®. Their address and the addresses of other fuse manufacturers are listed under Table III. The fuses must be mounted in series with each device.

In addition this chart lists the general gate requirements for the SCR's used in these assemblies. Commercial gate firing packages are available from Firing Circuits, Inc. Norwalk, Conn. 06852), Vectrol, Inc. (Rockville, Md.) and others. For additional information on selecting gate triggering requirements and designing gate drive circuitry refer to the Westinghouse SCR Gate Turn on Characteristics.

Also, listed in this table are RC dv/dt networks for dv/dt suppression. These RC dv/dt networks must be placed with short lead lengths across each device (rectifiers and SCR's) in the assembly. Only carbon or non-inductive wound power resistors and only extended foil AC voltage rated capacitors should be used.

R = Resistor (ohms)
P = Power Rating of Resistor (watts)
C = Capacitor (microfarads)
V = Voltage Rating of Capacitor (volts)

Electrical Data Number	Gate To Trigger Values @ 25°C	Recommended Gate Current @1.0 μsec (Rise Time)	I_{TSM} Surge (Amperes)				I^2t (Amp²-sec)	Line Voltage (Volts)	Fuse	RC dv/dt Network

Stud Mount ASSEMBLIES Gold Line

Mechanical Data

Tables V, VI and VII list the length, width and height, drill plan, mounting hole dimensions and approximate weight for each assembly. These tables are divided into "floor-type" mounting, "wall-type mounting", and "floor and wall type mounting", and must be used in conjunction with the mechanical key specified with each of the assembly type numbers.

Color coding for terminal identification is in accordance with NEMA standards.

Color Code: Yellow – A.C. terminals (input)
Red – Positive terminal (output)
Black – Negative terminal (output)

The material for Westinghouse Gold Line heat sinks is aluminum with gold chromate finish. Mounting feet and other mechanical support materials are of flame retardant, non-tracking, NEMA Class B (130°C continuous operation) insulation.

Thermal Data

Forced Air Cooling

The rating charts presented in this brochure cover natural convection and four forced air conditions: 150, 250, 400, and 1000 linear feet per minute (LFM). The air velocity is measured in LFM as it approaches the sink. From the rating charts, it can be seen that the current ratings of a given assembly can be increased considerably by using forced air. All air flow velocity measurements are per JEDEC RS-282, SEC 7-13.

The following is a partial listing of Manufacturers of blowers and fans:

1. W. W. Grainger, Inc.
   3812 Penn Ave.
   Pittsburgh, Pennsylvania 15201
2. Rotron, Inc.
   Woodstock, New York 12498
3. Rotating Components
   1560 5th Ave.
   Bay Shore, New York 11706
4. Pamotor, Inc.
   770 Airport Blvd.
   Burlingame, California
5. IMC Magnetics Corporation
   Eastern Division
   507 Main Street
   Westbury, New York

Oil Cooling

Current ratings for assemblies which are immersed in natural convected oil are approximately equivalent to the 1000 LFM air flow ratings listed in this catalog.

Disc ASSEMBLIES Air and Liquid Cooled

Ordering Information All assemblies in this section are keyed to a standard twelve digit part number which describes the assembly frame, heat sink, and device type. Simply insert the two digit voltage code for the desired assembly voltage rating.

Voltage Code Make sure the desired assembly voltage rating does not exceed the **Maximum Voltage Available** for the assembly under consideration. Then, using Table I, select the appropriate two digit voltage code. Inserting this two digit voltage code into the 9th and 10th positions of the assembly part number completes the required ordering information for all standard designs.

Available Circuits Table II lists the standard circuits available from Westinghouse. A complete index by circuit type is given on page A37. The shaded areas of Table II denote circuits with ratings published in this section. PC (positive center tap - common cathode connection) is available; use the corresponding single phase bridge data for the appropriate current rating. Likewise, the PN (negative centertap - common anode connection) is available; use the corresponding single phase bridge data for the appropriate current rating. Series and parallel circuits are also available.

Parallel Circuits This type of circuit is usually specified when paralleling two or more devices to obtain higher current ratings than available in a single device. Two common techniques for paralleling devices are direct and forced sharing; both techniques usually require specially factory matched test selection to assure proper device performance in the application. The standard Westinghouse PP circuit is provided with common anode connection; common cathode parallel circuit connections can be provided on request.

Series Circuit This type of circuit is usually specified when seriesing two or more devices to obtain higher voltage ratings than available in a single device. This type of circuit generally requires special QRR matching and other test matching to assure proper voltage sharing across each device in the application.

Standard air cooled assembly modules are only available for two devices in series. To order, simply specify PS frame connection. For current ratings, refer to the appropriate PR on PT circuit frame data; for assembly outline drawings, refer to the PD frame mechanical data.

Liquid cooled assembly ratings for two and three devices in series are presented in this section along with their outline drawings. For applications requiring four or more devices in series, consult Westinghouse for a custom module.

Liquid Cooled R/C Tabs Tab type, .250 push-on terminals are an option available on Westinghouse liquid cooled heat sinks. This option makes the connection of resistors, capacitors,and/or voltage protection devices directly across the semiconductor device an easy task. To order this feature, add suffix "RC" to the standard twelve digit type number - i.e. PDW6T6201230RC.

Kits and Sinks Standard air and liquid cooled disc assembly kits are available to the user who needs design flexibility on small quantity custom designs that might require non-standard factory configurations. Air cooled heat sink extrusions, designed by Westinghouse to optimize the cooling of large area power semiconductors. are available in mill lengths or cut-to-order lengths. See pages A65 and A66 for more information on Westinghouse kits and sinks.

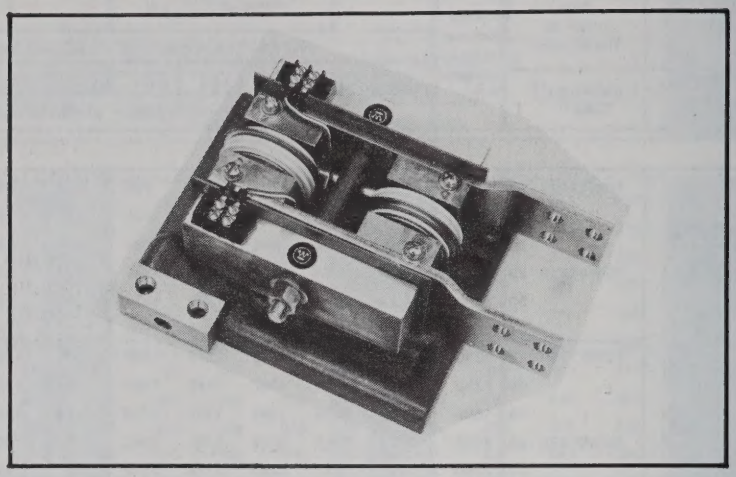
Disc Assemblies Manifold

- Eleven current ratings available
- Manifold base providing easy mounting and 18" isolating liquid path
- 3N221 and 3N222 types available
- ¼-18 N.P.T. (2) brass fitting supplied with grounding wire
- Water temperature sensing thermostats available for assembly protection



The Westinghouse AC manifold switch provides a fast-access, high performance assembly that has been rated for continuous or duty cycle applications. All mounting and electrical connections meet the JEDEC outlines. Water connections can be made (V) vertical or (H) horizontal. The electrical connections may be supplied either (S) short tangs or (L) tangs. Refer to Ⓦ outlines M-16 under mechanical data, this section.

AVAILABLE DESIGNS

FRAME	DEVICE	VOLTAGE		CURRENT		H_2O INLET	TANG
PAM7	T720	1000 through 2200	10 — 22	350 450 550	35 45 55	H V	L S
PAM9	T920	1000 through 3000	10 — 30	600 700 800 900 1000	06 07 08 09 10		
PAM9	T9G0	1000 through 3000	10 — 30	800 1000 1200	08 10 12		

Refer to Product Data Sections for complete device information.

Storage Temperature* ..... -40°C to 65°C
Maximum Ambient Temperature ..... 65°
Maximum Water Pressure (INLET) ..... 60 psig
Maximum Water Temperature (INLET) ..... 50°C
Maximum Pressure Drop, 1.25 GPM ..... 10 PSIG

*Manifold must be purged of water to avoid freeze up at low temperatures.

EXAMPLE: Obtain optimum device performance for your application by selecting proper order code PAM7 with T7201255 SCR's rated at 1240A RMS with 1.25 GPM t_{water} = 40°C and vertical H^2O connection, short tang electrical connections.

FRAME AND SINK TYPE				DEVICE TYPE				VOLTAGE CODE		DEVICE CURRENT		H_2O	TANG
P	A	M	7	T	7	2	0	1	2	5	5	V	S
1	2	3	4	5	6	7	8	9	10	11	12	13	14

HANDLING PRECAUTIONS:

When the switch is to be placed in operation, all surface moisture must be eliminated before power is applied, otherwise catastrophic electrochemical failure can be induced.

Coordination between cooling water temperature and the prevailing humidity is necessary to avoid condensation on water cooled metallic surfaces and electrical insulation. Ordinarily, this is no problem with 40°C cooling water. With lower temperature water, humidity control may be necessary to completely stop condensation.

MOUNTING POSITIONS: No restrictions

WATER QUALITY:

The cooling water shall have the following quality:

A neutral or slightly alkaline reaction, i,e, a pH between 7.0 and 9.0.

A chloride content of not more than 20 parts per million; a nitrate content of not more than 10 parts per million; and a sulphate content of not more than 100 parts per million.

A total solids content of not more than 250 parts per million.

A total hardness, as calcium carbonate, of not more than 250 parts per million.

No chemial additives to be used.

MOUNTING

Visually examine the switch before it is mounted to see that it has not been damaged during handling.

When mounting the insulating base, the following precautions should be taken to avoid distorting the plastic part, a cause of breakage and/or leakage.

The mounting surface is to be flat within .030".

Bolts or nuts which are used to hold the switch into the equipment shall be used with a flat washer against the plastic base. Torque values shall not be exceeded. (8ft-lbs. max. for ¼" screw).

For pipe connections, a sealing agent, joint compound, shall be used in order to limit the torque needed and in order to get a water -tight joint.

High Voltage Stacks, Rectifier
ASSEMBLIES
Channel Design

Features and Benefits
- Fully compensated modules for high reliability
- All terminations supplied for ease of installation
- Eight standard modules for wide range of current capability
- Vari-length channels for Package standardization
- High density packaging for compact designs
- Ratings for oil and air cooling
- Internal wiring available for complex circuit configurations
- Increased ratings by seriesing and/or paralleling individual channels
- Expert application assistance
- Special custom designs available on request

Applications
- RF generators
- Radio and TV transmitters
- Radar modulators
- Industrial precipitators
- Fusion and high voltage research
- Dielectric heating
- Voltage multipliers
- Electron Beam Welding

High Voltage Stacks, Rectifier
ASSEMBLIES
Channel Design

These modules, consisting of silicon diodes and compensating network, provide the optimum in steady state and transient voltage division. The design of the stacks provides for cooling by free convection air, forced convection air, or oil.

	2375A	3~
	1750A	10~

Notes:
- Mounting: Any position for oil cooling or forced convection; horizontal for free air convection.
- Max. ambient operating temperature for free air convection is based upon compensating network maximum ratings.
- Storage temperature: —55°C to 100°C.
- Surge ratings are per JEDEC and for non-repetitive applications. For repetitive faults, consult Westinghouse.
- JAN/military qualified Rectifiers are available on 9B11 modules.

* * This Design is also available with 6A Lead Mount Rectifiers — See next section.

22	20.00	508			

Example Required is a single phase bridge rated (with safety factor) at 15 KV per leg, I_{DC} output of 12 amps at 40°C ambient natural convection, and non-repetitive single cycle surge rating of 140 amps.

Step 1 **Select** Module for current and surge from information.

Result 7A12, this number is inserted as the 4 through 7 digits in the product description number.

Step 2 **Select** Cell voltage letter code from information. Note, highest voltage available would give most compact design but may affect delivery at times; also, the higher voltage cells operate the snubber components and diodes closer to maximum ratings. Z (1.0 KV), this letter code is inserted as the 8th digit in the product description number.

Step 3 **Obtain** Number of modules required per leg by dividing required voltage per leg (with safety factor) by module voltage (number of cells per module times cell voltage).

$$\frac{15\ \text{KV}}{1\ \text{Cell/Module} \times 1\ \text{KV/Cell}} = 15\ \text{modules}$$

Result 15 (9th and 10th digits of product description number).

Step 4 **Select (Trial I)** Circuit configuration available for your requirement; check Tables I and II for feasibility. This case, a *SB5* 7A1215, would not be feasible because 60 modules exceed the maximum channel length.

Select (Trial II) By dividing assembly into next standard circuit configuration, a doubler design (SD1 can be considered as indicated in Trial 1.

Result *SD1* works (1st, 2nd, and 3rd digit of the product description number). Two assemblies are now required for a complete single phase bridge.
Note: This assembly could have been reduced to single leg components by using the *SH1* circuit (four assemblies would then be required). The added cost for this is minimal and may be desired should parts or spares standardization be practical.

Step 5 **Calculate** Channel number using total number of modules per stack channel (N) and multiplying by module spacing factor (S) per Table II B, then adding the channel circuit factor (C) per Table II C. N = 15 modules/leg × 2 legs = 30 modules.
Channel number = (N×S)+C
= (30×1)+1 = 31.

Result 31 (11th and 12th digits of product description number).

Answer SD17A12Z1531 (Two doubler assemblies will be required for this single phase bridge example).

Step	4			1				2	3		5	
Product Description Number	Circuit			Module				Cell	Module/Leg		Channel Number	
	S	D	1	7	A	1	2	Z	1	5	3	1

Channel Design

Design Modules

These modules, consisting of silicon diodes and compensating network, provide the optimum in steady state and transient voltage division. The design of the stacks provides for cooling by free convection air, forced convection air, or oil.

Plate Design

Features and Benefits:
- Fully Compensated Modules For High Reliability
- Vari-Length Design For Circuit and Mounting Flexibility
- High Density Packaging For Compact Designs
- Ratings For Air and Oil Cooling
- Expert Applications Assistance
- Special Designs Available on Request
- High Repetitive Surge Ratings
- Compression Bonded Encapsulation For Thermal Cycling Capability
- Availability, Present High Volume Device Production

Applications:
- Fusion and High Voltage Research
- High Voltage Free-Wheeling Rectifiers
- Laser Supply Charging Diodes
- Magnetic Metal Forming Supplies

EXAMPLE: Required is a single phase bridge rated (with safety factor) at 60KV per leg, IDC output of 250 amps and a non-repetitive 3 cycle surge rating of 4500 amps (consult Ⓦ for repetitive surge applications).

STEP 1
SELECT — Module for current and surge from module electrical characteristics tables.

RESULT — B6C Module
B6C, This number will be inserted as the 4 through 6 digits in product description number.

STEP 2
SELECT — Call voltage code from design module cell types.

RESULT — 25 (2.5KV), This number code is inserted as 7 through 8 digits.

STEP 3
OBTAIN — Number of modules required per leg by dividing required voltage per leg (with safety factor) by module voltage (2 times cell voltage).

60KV (Total
5KV (Per Module) = 12

RESULT — 12 Modules, This number code is inserted as 9 through 10 digits.

STEP 4
SELECT — Circuit configuration available for your requirement by checking maximum allowed modules from Table II.

RESULT — HH1 configuration is the only available design. Four assemblies are required, HH1 is the 1 through 3 digits.

STEP 5
OBTAIN — High voltage stack length from Table II frame adder and module dimension adder.

RESULT — (HH1) 5.00" + .080" plus (12 modules) 25.13

$= 30.13 \begin{smallmatrix}+.093\\-.083\end{smallmatrix}$

RECTIFIERS

INTRODUCTION

Westinghouse introduced the first silicon rectifier in 1952. Today, Westinghouse offers a complete line of General Purpose and Fast Recovery rectifiers. All Ⓦ rectifier elements use N-type silicon providing soft recovery characteristics which minimize rectifier spike voltages and reduce transient protection requirements. Westinghouse uses an exclusive irradiation process to manufacture fast recovery rectifiers. This process provides precise control for better availability, soft recovery characteristics for less circuit ringing and reduced transient protection, high voltage capabilities up to 3200 volts with low reverse leakage currents, and fast recovery times — 200 nanoseconds for low current (6-30 ampere) rectifiers and 1.5 to 5.0 microseconds for high current (80-1400 ampere) rectifiers.

The axial lead mount package is the most popular for one to six ampere general purpose rectifier (diode) applications. The axial lead mount design features silver plated copper leads offering excellent heat conduction, solderability, and corrosion resistance. Several axial lead mount types are available with a chamfered body on the cathode end to insure proper polarity identification and correct assembly. Tape and reeling capability is available for those customers using automatic insertion equipment.

All stud mount rectifiers are available in **both** standard and reverse polarity. Color-coded glass or ceramic seals on all stud mount rectifiers make polarity identification easy and minimize the possibility of installing a device of the wrong polarity. Stud mount rectifiers (80 amperes and above) feature compression bonded encapsulation (CBE). This CBE package encapsulation technique reduces thermal fatigue inherent in conventional solder construction devices by eliminating solder joints.

Ⓦ disc mount rectifiers offer more amperes per dollar than any other package type. These devices feature double-sided cooling and have reversible mounting polarity. These all-copper non-magnetic packages are ideal in high frequency applications where magnetic noise can be a problem. In addition, the disc glazed ceramic seals are convoluted for long creepage paths which are especially important in applications where dirt, humidity and other contaminants can accumulate and cause arc-over.

Military rectifiers are available in both polarities in the popular stud mount DO-8 and DO-9 packages: JAN IN3289-95 series and JAN IN3164-74 series. Complete test facilities are available for matching devices for series and/or parallel operation, for special test parameter selection, and for full-scale high reliability requirements. Ⓦ offers a Lifetime Guarantee on all rectifiers bearing this symbol ✚. Specify Westinghouse Rectifiers.

How To Determine The Operating Junction Temperature of The Lead Mount Rectifier

When using a lead mounted rectifier as with all semiconductors, the maximum junction temperature should never be exceeded. The derating curves shown in graph A are the maximum currents at specified ambient temperatures when the lead mount is terminated in a heat sink within ½ inch of the body. When the lead mounted rectifier is terminated on a terminal strip, printed circuit board or is mounted in an enclosed area, the rectifier could be operating above or below the maximum junction temperature because of the heat sinking area.

To calculate the operating junction temperature, a lead temperature measurement must be made. First a thermocouple is soldered to the lead. A small amount of solder should be used, since excess solder will add to the area of the lead and will give erroneous readings. The thermocouple should be soldered 0.2 inch from the body of the rectifier. Excessive temperature and excessive time should be avoided when soldering to the rectifier lead.

Then the lead mount is operated at the maximum current encountered in the application and the lead temperature is stabilized. The temperature, forward voltage drop and current are recorded. The junction temperature is then calculated using the following formmula:

$$T_J = (T_A - T_{AO}) + T_L + (R\theta_{JL} \times P)$$

where T_J = Junction Temperature

T_A = Highest ambient temperature to be encountered in the application.

T_{AO} = The operating ambient temperature at which the lead temperature was measured.

T_L = Measured lead temperature

$R\theta_{JL}$ = The value obtained from Graph G for thermal resistance junction to lead at 0.2 inch from the body.

P = The average power calculated from the current and voltage readings.

If the lead temperature is measured at the maximum operating ambient temperature, the formula for calculating the junction temperature reduces to:

$$T_J = T_L + (R\theta_{JL} \times P)$$

Example:

The R340 lead mount rectifier is mounted on a printed circuit board to one inch square copper pads on each lead. The leads were ½" measured from the body of the rectifier to the printed circuit board. All measurements are made in accordance with EIA standard RS-282. The following was measured.

I = 6A Avg.
$V_{F(av)}$ = 1.1V
P = 6.5W
T_L = 123°C
$T_A = T_{AO}$ =25°C
$R\theta_{JL}$ = 9°C/W (From Graph G)

The junction temperature can be calculated as follows:

$$T_J = T_L + (R\theta_{JL} \times P)$$
$$= 123 + (9 \times 6.5)$$
$$= 181.5°C$$

This example shows that one inch square pads on each lead is not sufficient since the junction temperature exceeds the 175°C maximum. This junction temperature can be reduced by increasing the copper pads, by reducing the length of the leads or by increasing the air flow.

To take full advantage of the thermal transfer capabilities offered by the leads of lead mounted devices, the following are important points to remember:

- Avoid placing semiconductor devices which produce heat in locations where air circulation is restricted.
- Place heat-producing devices on top of a chassis, instead of below, and preferably on one that is vertically mounted.
- A 35-mil lead provides approximately 0.1 square inch of radiating surface per inch of length. For this reason one should not trim off needed cooling capacity.
- Terminal posts and mounting brackets frequently provide more cooling area than the device lead. If possible, take advantage of the cooling offered by terminals and mounting brackets. Mount heat-producing devices close to terminals or brackets.
- Check the ambient temperature inside cabinets. If it is excessive, install a fan: forced air can reduce thermal resistance by as much as 500 per cent.

Voltage–V_{RRM}

NOTES:
1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of this terminal is undefined.
3. ¼-28 UNF-2A. Maximum pitch diameter of plated threads shall be basic pitch diameter (.2268", 5.74 mm) Ref. (Screw thread standards for federal services 1957) Handbook H28 1957 P1.

Features:
- Diffused Junction
- Low Leakage Current
- Low V_F
- Lifetime Guarantee

Applications:
- Power Supplies
- DC to DC Converters
- Battery Chargers
- Magnetic Amplifiers

For JEDEC Reverse Polarity Add Suffix R, i.e., IN1191AR.

* Junction to Case	$R_{\theta JC}$	0.30
Case to Sink, Lubricated Mounting Surface	$R_{\theta CS}$	.15

• Ceramic seal supplied.

* JEDEC registered parameters.

Mounting: Recommended stud mounting torque; 360 in.-lbs. lubricated.

① Order reverse polarity units by designating R.
② Full cycle average measured with DC meter.
③ Ceramic package available.

RECTIFIER

160 A. Avg. Up to 1600 Volts — General Purpose Rectifiers IN3260,R - IN3276,R

Electrical Characteristics

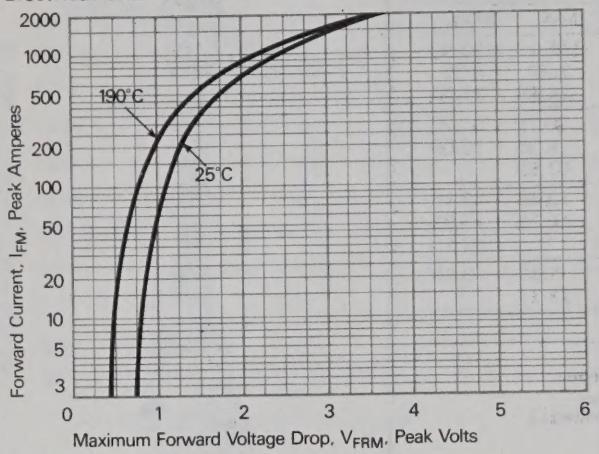

Figure 1. Forward current vs. forward voltage.

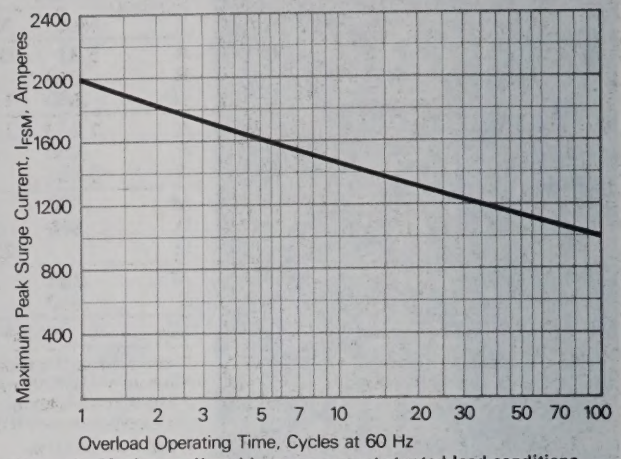

Figure 2. Maximum allowable surge current at rated load conditions.

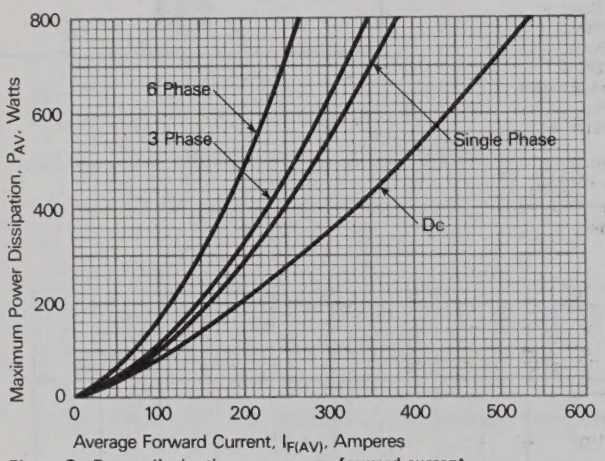

Figure 3. Power dissipation vs. average forward current.

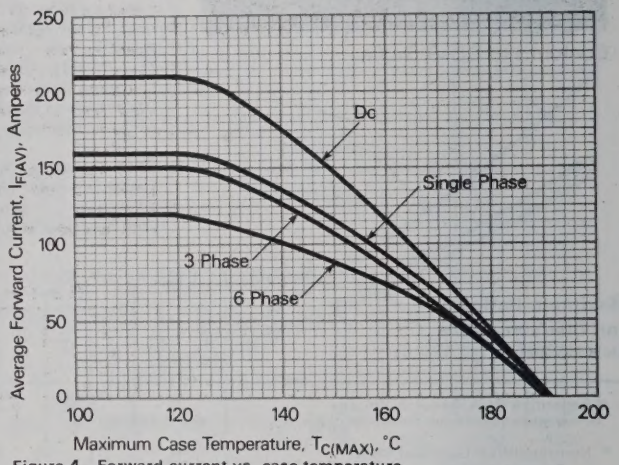

Figure 4. Forward current vs. case temperature.

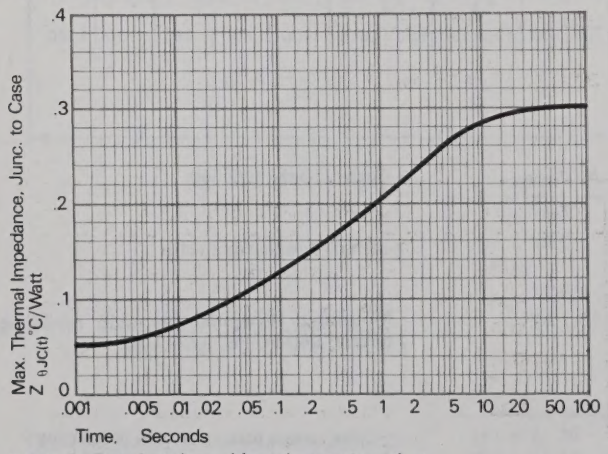

Figure 5. Transient thermal impedance versus time.

Features:

- Standard and Reverse Polarities with Color Coded Seals
- High Surge Current Ratings
- Electrical Selection for Parallel and Series Operation
- Compression Bonded Encapsulation
- Lifetime Guarantee

Applications:

- Welders
- Battery Chargers
- Electrochemical Refining
- Metal Reduction
- General Industrial High Current Rectification

General Purpose Rectifiers IN4044,R - IN4056,R

THYRISTORS
SCR's and RBDT's

INTRODUCTION

Westinghouse thyristors are designed, manufactured, and tested to insure the circuit designer "state-of-the-art" flexibility in design and dependability in operation. Westinghouse high power SCR's feature all-diffused elements and are available in a variety of packages: stud, disc, integral heat sink, and flat base. These SCR's offer high surge current capability with optimized forward voltage drops, soft firing and high di/dt capability with center-fired di/namic gate designs, and the industry's highest guaranteed dv/dt capability with shorted-emitter designs. All high power Westinghouse stud mount devices utilize compression bonded encapsulation (CBE) construction which reduces thermal fatigue by eliminating solder joints. Westinghouse disc devices feature non-magnetic packages and are cold-welded to avoid thermal stresses on the semiconductor elements during encapsulation.

Westinghouse Phase Control SCR's offer package I^2t or explosion ratings for most ceramic packages; in addition, surge suppression ratings are available which enable the designer to better utilize the full capability of Westinghouse SCR's. The Westinghouse T625 now offers the designer of a 150°C operating junction temperature SCR; this device features higher current ratings and better overload characteristics for motor control applications.

Westinghouse Fast Switching SCR's offer turn-off times as low 10 microseconds as a result of an exclusive irradiation process. These center-fired di/namic gate designs all feature low switching losses, high di/dt, low I_{GT}, high current, high voltage, low recovered charges, and fast turn-off times. The Westinghouse mid-gate structure (available only as a T72H or T9GH) is interdigitated gate design which optimizes the device for higher peak currents and narrower pulse widths while providing low switching losses and faster turn-on and turn-off capability.

The Westiinghouse Reverse Blocking Diode Thyristor (RBDT) offers the control of an SCR without the complex firing circuitry. This device blocks voltage in the forward direction until the appropriate dv/dt pulse is applied. The RBDT offers excellent di/dt capability up to 3,000A/us, and seriesing is easily accomplished for high voltage applications.

Westinghouse offers extensive testing capability for series and/or parallel matching, special parameter selection, or full high reliability screening. Westing- offers a Lifetime Guarantee on all SCR's bearing the symbol ✦. In addition, all Westinghouse thyristors are available on factory assembled and tested air or water cooled heat exchangers in a variety of circuit configurations. Specify Westinghouse Power Thyristors.

Creep & Strike Distance.
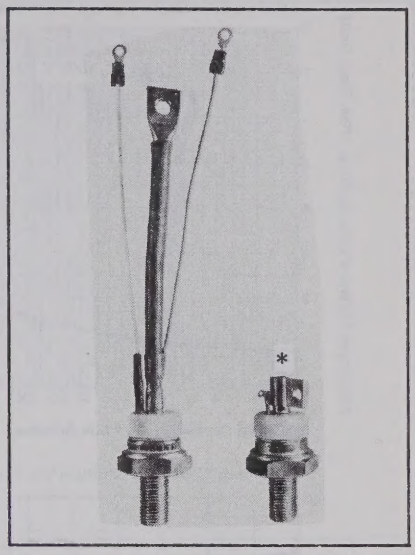
.50 in. min. (12.85 mm).
.10 in. min. (2.54 mm). **
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—5 oz. (142 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of terminals is undefined.
3. Pitch diameter of ½-20 UNF-2A (coated) threads (ASA B1.1-1960).
4. Dimension "J" denotes seated height with leads bent at right angles.



* For TO-83 Outline, see page S23.

Features:
- All diffused design
- Low gate current
- Low V_{TM}
- Compression Bonded Encapsulation
- Low Thermal Impedance

Applications:
- Phase control
- Power supplies
- Motor control
- Light dimmers

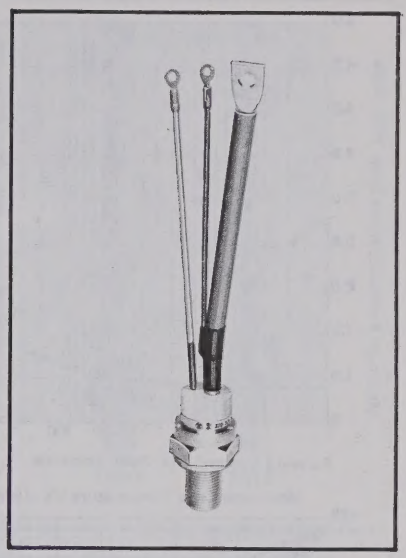
ϕT	.260	.290	6.60	7.37
Z	.340		8.64	
ϕW	¾-16 UNF-2A			

Creep & Strike Distance:
.69 in. min. (17.60 mm).
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—8 oz. (227 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of terminals is undefined.
3. Pitch diameter of ¾-16 UNF-2A (coated) threads (ASA B1.1—1960).
4. Dimension "J" denotes seated height with leads bent at right angles.



Features:
- Center fired di/namic gate
- All diffused design
- Guaranteed dv/dt (300 v/μs)
- Low gate current
- Low V_{TM}
- Low thermal Impedance
- High surge current capability
- Compression Bonded Encapsulation
- Lifetime Guarantee

Applications:
- Phase Control
- Power Supplies
- Motor Control
- Light Dimmers

Creep Distance—.80 in. min. (20.32 mm).
Strike Distance—1.02 in. min. (25.91 mm).
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—16 oz. (454 g).
1. Dimension "H" is a clamped dimension.

Package I^2t (Case rupture) rating:
90×10^6 A^2sec.

Features:
- Center fired di/namic gate
- All diffused design
- Guaranteed dv/dt (300 v/μs)
- Low gate current with soft gate control
- Low V_{TM}
- Low Thermal Impedance
- High surge current capability
- Westinghouse Lifetime Guarantee

Applications:
- Phase Control
- Motor Control
- Power Supplies

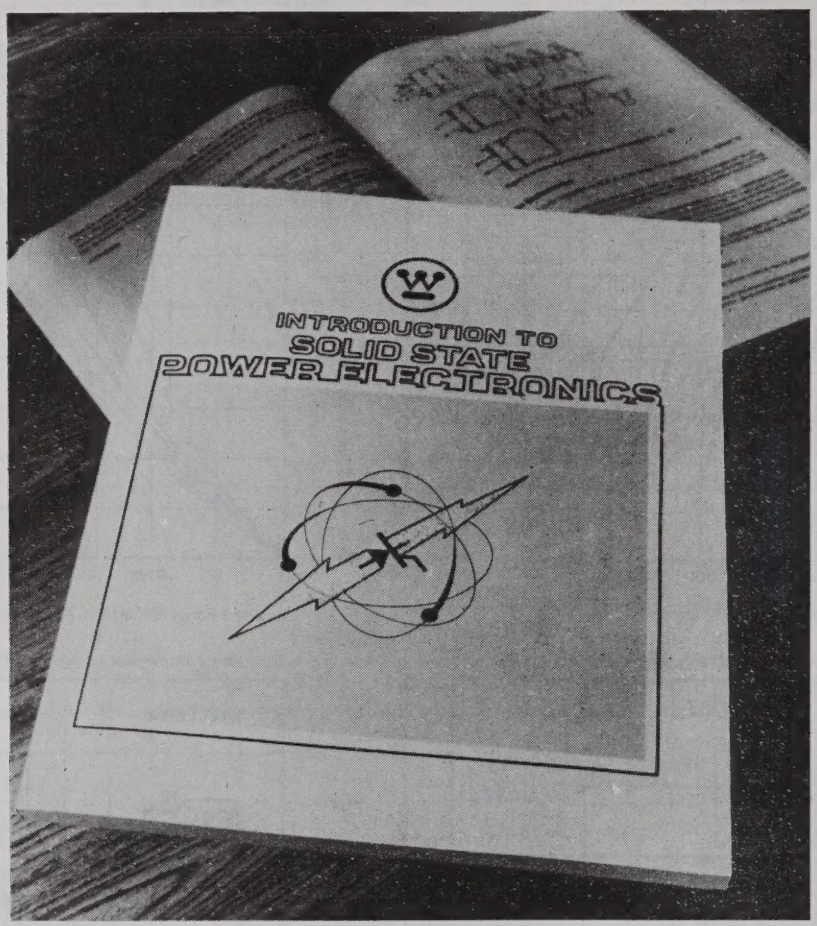
Introduction to Solid State Power Electronics



- **8½ x 11 Format**
- **144 Pages**
- **$6.00 U.S. (Includes Book Rate Postage)**
- **$6.50 Elsewhere (Includes Book Rate Postage)**

With the growing importance of power electronics, persons with a basic knowledge of electrical engineering, both in industry and at the university, should find this text a worthwhile investment.
Approved text for IEEE short course in Solid State Power Electronics and numerous college and university courses.
Volume educational and quantity discounts are available.
Book describes device characteristics and fundamental circuit principles needed to fully comprehend the field of power electronics. Included are numerous references for more detailed research and example problems which illustrate the essential mathematical relationships in power electronics.

Note: High frequency sine and square wave data available, consult factory.

Features:

- Center fired di/namic
- High di/dt with soft gate control
- High frequency operation
- Sinusoidal waveform operation to 20 KHz
- Rectangular waveform operation to 20 KHz
- Low dynamic forward voltage drop
- Low switching losses at high frequency
- Lifetime Guarantee

Applications:

- Inverters for
  UPS
  Induction Heating
  AC Motor Control
- Switching power supplies
- Cycloconverters
- Choppers
- Crowbars

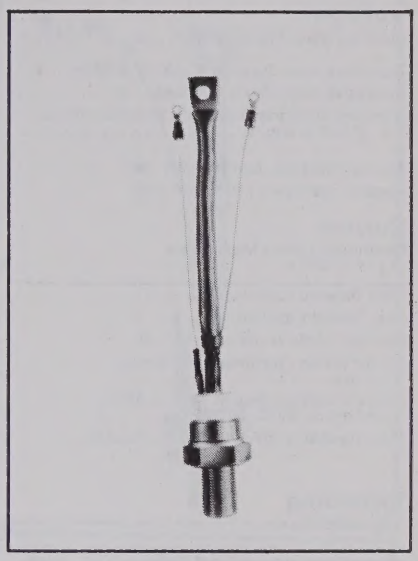
Creep & Strike Distance:
.69 in. min. (17.60 mm).
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—8 oz. (227 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of terminals is undefined.
3. Pitch diameter of ¾-16 UNF-2A (coated) threads (ASA B1.1—1960).
4. Dimension "J" denotes seated height with leads bent at right angles.



Note: High frequency sine and square wave data available, consult factory.

Features:
- Center fire, di/namic gate
- High di/dt with soft gate control
- High frequency operation
- Sinusoidal waveform operation to 20 KHz
- Rectangular waveform operation to 20 KHz
- Low dynamic forward voltage drop
- Low switching losses at high frequency
- Westinghouse Lifetime Guarantee

Applications:
- Inverters for
  UPS
  AC motor control
  Induction heating
- Cycloconverters
- Choppers

THYRISTOR

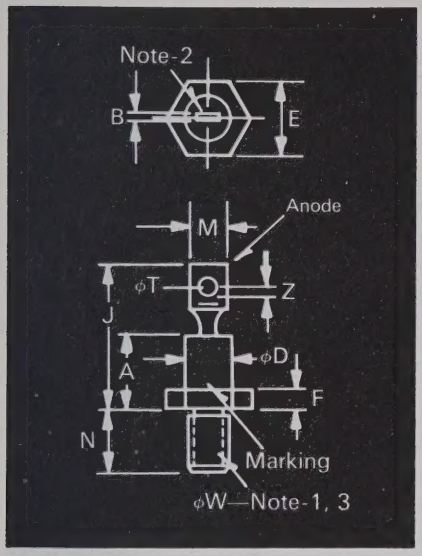
Reverse Blocking Diode Thyristor
RBDT
T40R

22 A Avg.
Up to 1000 Volts



Conforms to DO-5 Outline

Features
- di/dt of 2000 to 4000 A/us
- compression Bonded Encapsulation
- All Diffused Design
- Low V_{TM}
- JEDEC DO-5 Package

Applications:
- Radar Modulators
- Laser Pulsers

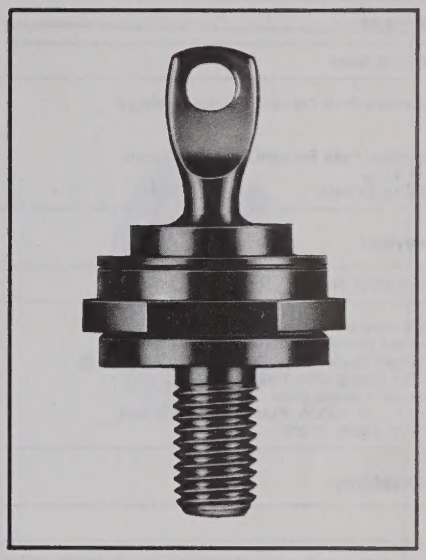
Glass To Metal Seal—
Creepage & Strike Distance = .09 in. min. (2.46 mm)
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—.6 oz (18g)

NOTES:
1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of this terminal is undefined.
3. ¼-28 UNF-2A. Maximum pitch diameter of plated threads shall be basic pitch diameter (.2268″, 5.74 mm) Ref. (Screw thread standards for federal services 1957) Handbook H28 1957 P1.



Application

The reverse blocking diode thyristor is a two-terminal, four-layer PNPN switch. In the forward direction, the device will initially block voltage to its rated V_{DRM}. However, upon application of a trigger voltage, it switches to a low impedance state where it remains until the anode current is reduced below the holding current.

The T40R employs an all diffused design and is packaged in the standard DO-5 outline case. The exclusive Westinghouse CBE (compression bonded encapsulation) construction technique is employed to eliminate solder joints and, thereby, failures caused by thermal fatique.

These devices are ideal for pulse work because of their high di/dt and fast switching capabilities. Radar modulators and laser pulsers are two prime examples of the kinds of applications particularly suited to the Westinghouse T40R.

THYRISTOR

TRANSISTORS

INTRODUCTION

Ⓦ offers a wide range of power transistors designed to match the equipment manufacturer's technical and economic requirements. The designer can choose from various processes, ratings, and package styles to optimize an application: general purpose single-diffused types for economical ruggedness; high S.O.A. alloy types for the ultimate in reliability; and high power, fast switching tripled-diffused types for "state-of-the-art" voltage and power capability.

For linear applications (amplifiers and regulators), general purpose transistors in TO-66 and TO-3 packages offer the most "watts per dollar" value. Excellent Safe Operating Area (SOA) make these types ideal for inductive loads such as DC motor controls or 60 and 400 hertz inverters.

High S.O.A. alloy process transistors from Ⓦ have been used in numerous critical aerospace and defense programs. Alloy construction, hard solder/moly bonding, and hermetic,copper stud, cases have generated a record of superb performance and reliability. For inductive load switching, the forward and reverse bias Safe Operating Areas (SOA) of these devices make alloy the clear choice over other processes.

The newest addition to the Ⓦ transistor line is the super-powered family of triple-diffused switching types. Up to 500 volts of sustaining voltage capability is coupled with a gain rating at 50 amperes; but brute power is not the only feature of the D60T family — switching times under a microsecond and Compression Bonded Encapsulation (CBE) open a new area of application for designers of high speed inverters, switching regulators, AC motor drives and VLF radio transmitters.

Complete test facilities are available for matching, special selection, or high reliability screening. Ⓦ offers a Lifetime Guarantee on all transistors bearing this symbol✤. Specify Westinghouse Power Transistors.

Finish—Nickel Plate.
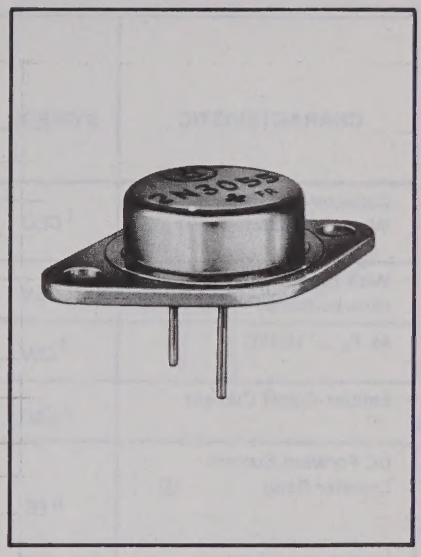
Approx. Weight—.58 oz. (16.5 g).



Conforms to TO-3 Outline

Features:
- High reverse bias S.O.A. for inductive loads
- Low thermal resistance
- Hermetically sealed TO-3 type package
- 117 watt dissipation
- 100% Power tested
- Lifetime guarantee

Applications
- Series and shunt regulators
- High-fidelity amplifiers
- Power switching circuits
- Solenoid drivers

Finish—Nickel Plate.
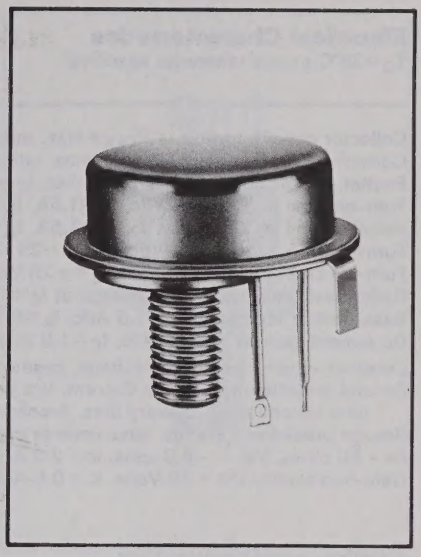
Approx. Weight—.9 oz. (25 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Contour and angular orientation of terminals is undefined.
3. Pitch diameter of 5/16-24 UNF-2A (coated) threads (ASA B1.1-1960).



Features:

- Gold Alloy Process
- No forward bias secondary breakdown to 150 volts
- High reverse bias S.O.A. for inductive loads
- Low thermal resistance with copper base
- 175 watt dissipation
- Protection from thermal fatigue with hard solder and molybdenum construction
- 25 volt V_{EBO}
- Low $V_{CE(sat)}$
- Lifetime Guarantee

Applications:

- High Power Switching
- Amplifiers
- Servo Systems
- Regulators
- Modulators

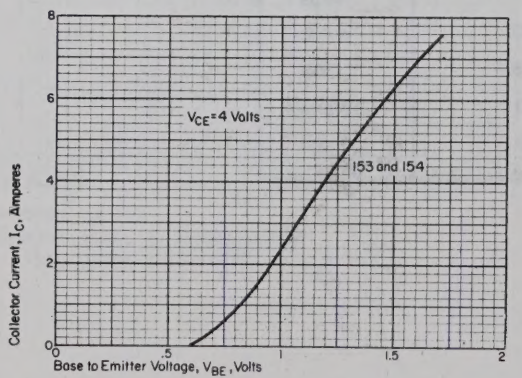
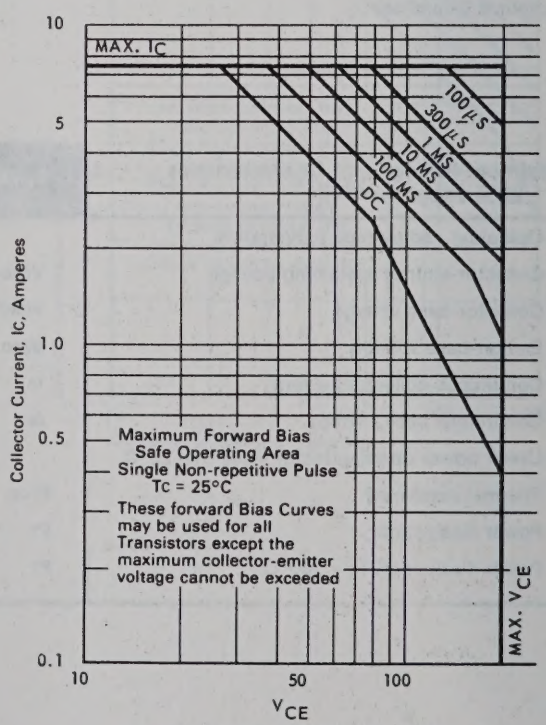
Typical dc gain versus collector current T_C = 25°C.

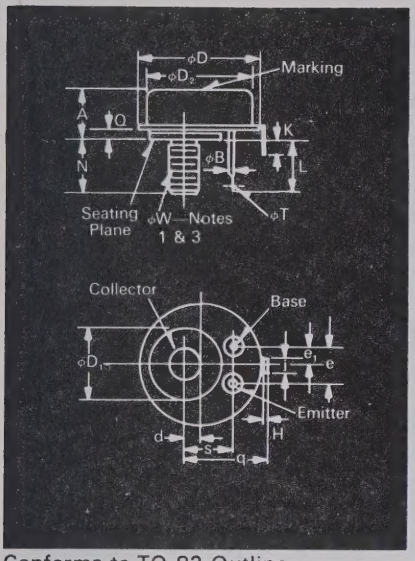




TRANSISTOR

NPN Power TRANSISTORS 2N1015/2N1016

7.5 Amperes 30-250 Volts



Conforms to TO-82 Outline

Features:

- Gold Alloy Process
- No forward bias secondary breakdown to 100 Volts
- High reverse bias S.O.A. for inductive loads
- Low thermal resistance with copper base
- 150 watt dissipation
- Protection from thermal fatigue with hard solder and molydenum construction
- 25 volt V_{EBO}
- Low $V_{CE(sat)}$
- Lifetime Guarantee

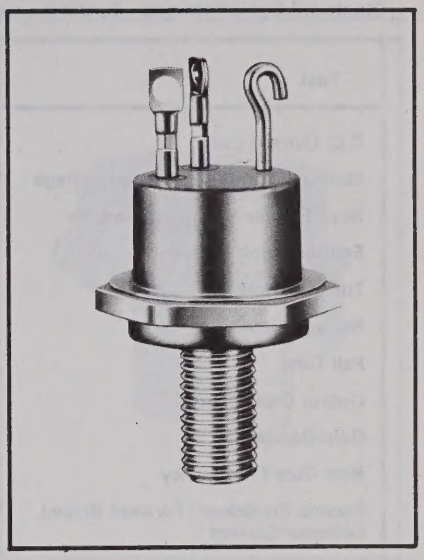
φW	5/16-24 UNF-2A			

Finish—Nickel Plate.
Approx. Weight—1 oz (28 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Contour and angular orientation of terminals is undefined.
3. Pitch dia. of 5/16-24 UNF-2A (coated) threads (ASA B1.1-1960).



Conforms to MT-33 Outline

Features:

- Gold Alloy Process
- No forward bias secondary breakdown to 67 volts
- High reverse bias S.O.A. for inductive loads
- Low thermal resistance with copper base
- 150 watt dissipation
- Protection from thermal fatigue with hard solder and molybdenum construction
- 25 volt V_{EBO}
- Low $V_{CE\ (sat)}$
- Lifetime Guarantee

Applications:

- High Power Switching
- Amplifiers
- Servo Systems
- Regulators
- Modulators

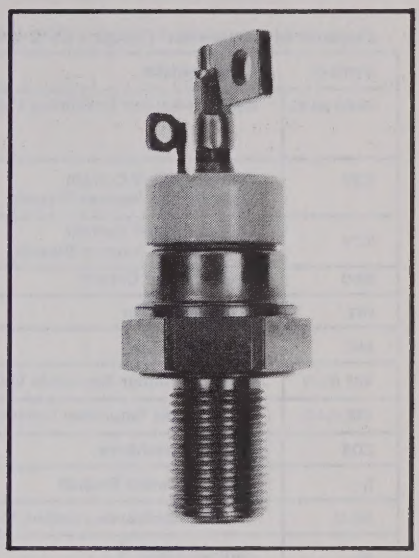
Creep & Strike Distance.
D60T - .690 in. min. (17.60 mm).
(In accordance with NEMA standards.)
Finish—Nickel Plate.
Approx. Weight—8 oz. (227 g).

1. Complete threads to extend to within 2½ threads of seating plane.
2. Angular orientation of terminals is undefined.
3. Pitch diameter of 3/4-16 UNF-2A (COATED) threads (ASA B1.1-1960).



Maximum Ratings
Collector Current (peak): 200 Amperes
Collector Current (continuous): 100 Amperes
Base Current (continuous): 20 Amperes
Power Dissipation: 625 Watts at Tc = 75°C
Operating and Storage Temperature: -50°C to +200°C

Applications
- High Frequency Inverters
- Motor Controls
- Switching Regulators
- VLF Transmitters

Features
- Triple Diffused Design
- CBE Construction
- 625 Watt Power Capability

Ordering Information
